AN ABSTRACT OF

A Clinical Lecture

ON

THE APPLICATION OF SUTURING TO THE VASCULAR SYSTEM,

INCLUDING ONE CASE OF SUTURE OF A WOUND OF THE HEART AND TWO OF WOUNDS OF ARTERIES.

Delivered at the London Hospital

By RICHARD WARREN, M.D., M.Ch. Oxon., F.R.C.S. Eng.,

SENIOR SURGEON TO THE CHILDREN'S HOSPITAL, SHADWELL; ASSISTANT SURGEON TO THE LONDON HOSPITAL, E.

Gentlemen,—Within the last 20 years, especially in the last decade, the technique of suturing, so successful in the surgery of the abdominal viscera, has been serviceably employed in dealing with conditions of the vascular system, and it is to this branch of vascular surgery that attention is directed, exemplifying it with details of three cases which have come under treatment during the last few years.

There are three main difficulties to be encountered in the practice of suturing blood-vessels: (*a*) Hæmorrhage, which is overcome by very accurate suturing; (*b*) thrombosis, due to the effect of interposing foreign bodies (in the form of sutures) in the blood stream—this ill-effect is minimised by the use of suture material steeped in liquid vaseline; and (*c*) infection, which leads to thrombosis and disintegration of the tissues sutured, and spoils all hope of success, indicating the need for the most rigid asepsis in these operations.

Operations on the vascular system may be divided into intra- and extra-thoracic. In the former group we find attempts to suture wounds of the heart which have proved on the whole most successful. Attempts to remove emboli from the pulmonary artery, though successful experimentally (Trendelenburg), have not at present been brought to a successful issue in the human subject.

Wounds of the Heart.

These fall into two main groups according to the size of the wound in the thoracic wall and pericardium.

1. Where the wound in the latter is large and widely open and there is a penetrating wound of the heart of any size, death from uncontrollable hæmorrhage will be so speedy that opportunities for surgical interference can hardly arise, except in such exceptional cases as that described by Travers where the penetrating object remained in the wound and effectively plugged it.

2. A more usual condition is where the external wound is small and slit-like, as from a stab, and consequently the blood effused from the wounded heart cannot escape from the pericardium, but remains pent up in this cavity. Many such cases have been reported in America and the continent, but in this country they are rare. This collection of blood in the pericardium results in the heart being gradually compressed, and as the cavities of the heart are thus diminished in size, less and less blood is driven out with each beat till finally the amount is insufficient to support life. This weakening of the heart beat naturally diminishes the amount forced into the pericardium, so that such patients may live many hours after the injury; instances up to 24 hours are reported. The cases I have actually seen came under observation two to four hours after being stabbed. The clinical picture of this slow compression of the heart by effusion into the pericardium, which has been described as "heart tamponade," better "cardiac compression," is important to recognise since external bleeding may be minimal, nor does internal hæmorrhage often occur unless wounds of the pleura, lung, or abdominal viscera complicate the lesion.

The diagnosis of traumatic hæmo-pericardium and "cardiac compression" rests on (*a*) finding a wound over the præcordium, and (*b*) on the general symptoms of the patient, since local signs pointing to the condition, such as an increased area of cardiac dulness, diminished strength of the heart sounds, or adventitious sounds, may be quite unnoticeable.

(*a*) The wound will probably be quite small and with little or no external bleeding, and is likely to be tortuous and narrow, so that no amount of probing will show the depth to which it has penetrated.

(*b*) The general condition of the patient is peculiar and may be described as one of "irritable shock." The face is pale, drawn, and haggard, the mental attitude querulous and irritable, much complaint being made of pain over the præcordium. The pulse is small and rapid; respiration is but little affected. To conclude, where there is a wound over the heart of a patient who is suffering from severe constitutional depression the pericardium should be explored.

Exploration of the Pericardium.

Where the signs point to hæmo-pericardium only it will suffice to turn out a flap of soft tissues over the fourth and fifth right rib cartilages and the half sternum opposite these, removing the cartilages and half sternum. Where further injuries to lung, &c., are suspected it will perhaps be safer to employ positive-pressure insufflation anæsthesia and open the thorax widely along the fifth costal space, separating the ribs with suitable retractors. The fibrous scar resulting after the rib cartilages are removed is quite strong enough for practical purposes. Having exposed the pericardium the presence of blood is easily recognised by the tenseness of the sac, the impaired action of the heart, and the dark colour of the contained blood seen through the translucent wall. When in doubt a small incision through the wall of the pericardium will permit egress to the contained blood, and if the patient's condition is bad will relieve the pressure on the heart.

The next step is to open the pericardium freely and search for the wound in the heart; free bleeding may render this somewhat difficult. Having found the aperture it should be temporarily secured with catch-forceps and sutures passed taking up the whole thickness of the wall of the wounded portion. Ordinary silk sutures have proved successful, but to prevent thrombosis and pulmonary embolism vaselined sutures would be an improvement, since both cases coming under notice developed signs of embolism after some days. The pericardium should be closed without drainage, and the skin flap sutured in place, a drain tube passing down to the pericardium for 24 hours.

No. 4753.

CASE 1. *Stab wound of the right ventricle treated by suture.*—A male, aged 48, fat and flabby in build, had been stabbed over the heart four hours previously. A small linear wound ¾ inch long (which did not appear to be deep) was found over the præcordium, while external bleeding was minimal. The patient complained much of pain over the heart, was pale and anxious, with a small feeble pulse of 120; the area of cardiac dulness was perhaps slightly increased, and the heart sounds were feeble, but no adventitious sounds were heard. From the position of the wound and the amount of shock a diagnosis of hæmo-pericardium was made. The pericardium was explored by turning up a flap of soft parts and removing the cartilages of the fourth and fifth left ribs with half the sternum opposite these. The intercostal and internal mammary vessels were tied and the triangularis sterni displaced. The pericardium was tense, dark in colour, and the cardiac impulse obscured. The pericardium was freely opened, much blood escaping, and a wound 1¼ inches long in the anterior surface of the right ventricle was secured with catch forceps and sutured with five stitches of silk. The pericardium and skin were sutured as already described. The wound healed by first intention, and with the exception of slight left pneumothorax (due to tearing the pleura at the exploration) and a little femoral thrombosis, uneventfully. The patient was demanding work a year after, and three years later was alive and active.

SUTURING OF EXTRATHORACIC VESSELS.

Suturing operations on the extrathoracic vessels are confined to the larger sort, being impracticable and unnecessary in those smaller than the brachial, carotid, or femoral arteries. Blood-vessels may be sutured for (*a*) injuries, (*b*) in the treatment of aneurysms, and (*c*) to reverse the circulation in parts where the arterial circulation is becoming impaired.

Injuries of Blood-vessels.

In the case of injuries we may simply suture a cut in the wall of the vessel or perform an end-to-end anastomosis, or even by means of a double end-to-end anastomosis graft a portion of vein into a gap formed by the destruction of a considerable part of an artery.

The method of Carrel is the most practical for performing end-to-end anastomosis; the chief points in the technique are as follows:—1. Very fine silk sterilised in vaseline and the finest needles are employed. 2. The edges to be sutured are not bruised with forceps, but the needle is passed straight through. 3. Blood is prevented from escaping into the field of operation by placing rubber-faced clamps on the vessel above and below the site of anastomosis. 4. Blood and clots are washed out of the portions to be anastomosed with saline and the former touched with liquid vaseline. 5. The vessel is freed from its sheath for a sufficient distance (½ inch) and guide sutures are introduced (three in number) at equidistant points of the circumference of the ends to be united. These guide sutures are taken in pairs, tied, and gently pulled, thus rendering the part of the cut edges between straight, parallel, and everted. A continuous suture then closes the lines thus formed —i.e., the circumference is united by three continuous sutures, each taking up exactly one-third of the circumference, and thus bringing the edges together in an everted position, intima to intima. Having completed the entire line of suture the distal hæmostatic clamp is removed and blood enters from the lower end of the artery under low pressure. Some leakage takes place through the stitch holes, but this is checked by pressure with gauze for a minute. After removing the upper clamp the adventitial sheath is closed, and the overlying tissues are sutured in layers.

CASE 2. *Excision of an injured portion of the femoral artery, with end-to-end anastomosis.*—A youth, aged 17, was hit at 50 yards by the bullet from a small revolver which entered the apex of Scarpa's triangle; there was but slight bleeding and nothing pointing to arterial injury. The bullet was located with X rays and exploration made within 12 hours of the injury. On tracing the course of the bullet the latter was found to have penetrated the sartorius, and on enlarging the incision and retracting the latter muscle it was found that the femoral sheath had been pierced. The femoral artery was stained with lead on its outer surface and slightly dilated at the point of impact. The bullet was later run to earth in the adductor muscles, and together with portions of nether garments was removed.

On closer examination the artery was found to be thinned at the point of dilatation. This made it tolerably certain that the inner coats had been ruptured, or, in other words, that there was an early condition of traumatic aneurysm. Two courses seemed possible, either to tie the vessel above and below the site of injury, thus obliterating its lumen, or to remove the injured portion and perform end-to-end anastomosis. As the latter course seemed more conservative rubber-covered intestinal clamps were applied above and below the injured portion, incidentally tying a small collateral branch, and half an inch of the vessel was excised. On examining the excised part it was found to be split through the inner and middle coats for nearly the whole circumference of the artery, only the outer coat remaining intact. The cut ends were sutured by the technique described above, and although there was some narrowing at the site of suture the dorsalis pedis artery could be felt pulsating after the operation. The wound healed by first intention, and ten days later the pulse could be felt feebly in both the dorsalis pedis and posterior tibial artery. The return of power to the limb was quite good and the circulation satisfactory, though it is, of course, impossible to say whether the pulse was really due to transmission through the sutured portion or from increase of the collateral circulation.

Aneurysms.

The application of suturing to the treatment of aneurysms is largely due to the work of Matas, who has shown the great possibilities of his method. The main plans of treating aneurysms may be mentioned:—

(*a*) Excision of the aneurysmal sac and ligature of the arteries which feed it. Very rarely a small or early aneurysm may be excised and the artery reconstructed by end-to-end anastomosis as in the case just described.

(*b*) Obliteration of the sac (the most generally useful method), which may be accomplished:—1. By increasing the tendency of the blood to clot either generally, as by starvation and administering iodides, or locally by irritating the interior of the sac (Macewen), introducing foreign bodies with or without electrolysis (Moore, Conradi, Power), or diminishing the rapidity of the blood stream through the sac as by the various methods of ligature, proximal or distal, partial or complete. 2. By opening the sac, turning out clots, and tying or suturing all vessels leading into the sac. The underlying principle is equally in view both in the "old operation," where the sac was laid open without preliminary hæmostasis, the surgeon relying on his manual dexterity to find, control, and tie the "feeding" arteries of the sac before the patient bled to death, and in the operation of Matas.

The last method may fairly be called the "new operation," and is a natural advance on the older plan due to application of preliminary hæmostasis and asepsis. The blood-supply to the sac is controlled by tourniquet or temporary clamps on the main artery above and below the sac; the latter is opened, clots removed, and all the orifices leading into the sac securely sutured, the suture line being reinforced by invaginating the whole sac with sutures introduced from its interior till a solid mass is formed.

In general it may be taken as an axiom that where the wall of the vessel is diseased obliteration or excision of the sac is essential for cure, though palliation (often of long duration) may be attained by increasing the thickness of the sac wall by promoting clotting and fibrosis.

(*c*) By repairing the vessel, which is only feasible where the latter has given way at one point and is not generally diseased and dilated, or, in other words, in some instances of traumatic or false aneurysm, in which case the operation really is one of suturing a wound in the arterial wall. The following case is an example of the last method.

CASE 3. *Punctured wound of the brachial artery resulting in false aneurysm treated by suture.*—A lad aged 15 was stabbed with a knife on the inner side of the left arm; the skin was sutured and healed by first intention. During the next six weeks a swelling developed in the region of the stab, slowly increasing in size, and when the patient came for advice this extended the whole length of the inner side of the arm, as a tense, fluctuating, pulsatile swelling; the radial pulse below was imperceptible. In addition there was anæsthesia of part of the thumb and the first three fingers, together with weakness of the flexors of the wrist and fingers and of the short muscles of the thumb supplied by the median nerve, pointing to an extensive but incomplete lesion of that nerve.

At operation, after applying a tourniquet, the swelling was laid open and proved to be a thin-walled cyst filled with blood and clots, communicating with the brachial artery throught a slit about ½ inch long. The median nerve was flattened and thinned over this false aneurysm, but not divided. It had been hoped to close the wound in the artery and thus restore its lumen, but it chanced that the vessel had become impervious below the site of injury so that suturing the vessel (which was performed) simply cured the aneurysm, the vessel remaining impervious in its lower portion. The wound healed by first intention, and some months later there was no evidence of return of the aneurysmal swelling, while the lesion of the median nerve was gradually recovering.

(*d*) Reconstruction of an artery, affected by fusiform aneurysm, by suturing hardly demands mention, as our knowledge of the causation of this condition renders operative measures short of obliteration most unlikely to be successful, since the already diseased wall will surely give way again.

Arterio-venous Anastomosis.

Time and space will not permit of more than mere mention of the use of arterio-venous anastomosis and reversal of the circulation, with view of improving the blood-supply to parts threatened with incipient gangrene (usually the leg). Since successes (often qualified) are reported in some instances the method seems likely to have a limited use in carefully selected cases. The most suitable technique seems to be to perform a lateral anastomosis of artery and vein, together with ligature of the vein above the stoma, thus allowing of two routes by which the blood may reach the periphery.

The respectable amount of success attained in these cases by adopting the method of suturing renders the publication of the above series of special interest at this time, when amongst other wounds those involving the vascular system may, in large numbers, come under the care of surgeons.

ON THE VALUE OF ANTISTREPTOCOCCAL SERA.[*]

BY JAMES WALTER McLEOD, M.B., CH.B. GLASG.,
ASSISTANT LECTURER IN PATHOLOGY, CHARING CROSS HOSPITAL MEDICAL SCHOOL.

A STRAIN of streptococcus which I met in the course of my work was found to possess high virulence for rabbits combined with a very striking power of producing hæmolysis in these animals before death. It appeared to me to afford a good opportunity for testing the value of some of the commercial antistreptococcal sera, since there are few subjects in the whole range of bacteriology and therapeutics with regard to which a more confusing diversity of opinion exists than that of the value of serum treatment in streptococcal infections. Before going into this literature I shall record the results of my own experiments so as to be able to discuss them together with those of other investigators.

The strain of streptococcus in question had been originally isolated at a post-mortem examination from the spleen of a patient who had suffered from an obscure anæmia and was found at death to have vegetations on her mitral valve. After it had been subcultured on ordinary agar for two years it was passed through three rabbits in succession, and the strain from the third passage, which killed a rabbit in the dose of 0·005 c.c. but not in that of 0·001 c.c., was used in all the experiments without further subculture—that is to say, that all the cultures in fluid media used for injection of the rabbits were inoculated from an agar tube which had been smeared with the heart blood of the third passage rabbit and kept in the ice chest after a preliminary incubation of 18 hours. The medium used for the culture of the streptococcus consisted of 7 parts of ordinary bouillon and 3 parts of horse serum. The horse serum had been heated for 1 hour at 57° C., and then stored in sterile tubes for some weeks. The dose was in every case 0·5 c.c. of a culture which had been incubated for 12–13 hours—i.e., about 200 times the minimal lethal dose; it was administered subcutaneously. The serum used as a remedy was introduced directly into the general circulation through a vein in the ear, and in one or two instances this treatment was supplemented by a subcutaneous injection. The experimental animal was always the rabbit. A double control was made in each

TABLE I.

Experimental animal.	Treatment.	Result.
A.	8 c.c of antistreptococcal serum 15 min. before injection of culture.	Died within 40 hrs.*
B.	8 c.c. of antistreptococcal serum 4 hrs. after injection of culture.	,, after 49 hrs.
C.	Ibid.	,, ,, 52 hrs.
D.	8 c.c. of antistreptococcal serum 10 hrs. after injection of culture.	,, within 40 hrs.*
1st control.	8 c.c. of heated normal horse serum 4 hrs. after injection of culture.	,, after 75 hrs.
2nd control.	No treatment.	,, within 40 hrs.*

* As these animals died during the night the exact number of hours which elapsed before death occurred was not ascertained.

---

[*] The expenses in connexion with this investigation have been mainly defrayed with the help of a grant from London University under the Dixon Fund. I have pleasure in acknowledging my indebtedness to the trustees of this fund.

experiment; one rabbit was treated with the heated normal horse serum used in preparation of the culture medium and a second received no treatment. The first experiment was carried out with the fresh serum, free from preservative, of one of the horses from which Messrs. Burroughs, Wellcome, and Co. obtain their polyvalent antistreptococcal serum.

A certain caution must be exercised in drawing conclusions from any experiments such as these on account of the varying individual resistance of the rabbits; the large dose of culture employed in these experiments, however, reduces this factor of variability considerably, and the conclusions to be drawn from the above experiments are probably accurate. They are, that both before and 10 hours after the injection of the culture little benefit is derived from the serum treatment in these conditions of experiment, but that four hours after injection of the culture treatment with serum has some effect in checking the infection and prolonging life. With this result in view a second experiment was undertaken in which specimens of antistreptococcal serum, in the form in which they appear in the market and are used clinically, were tried. Two of these were sera widely used in Britain and America—those of Messrs. Burroughs, Wellcome and Co. and Messrs. Parke, Davis and Co.—and the third was that of the Höchst Farbwerken prepared by Dr. Meyer and Dr. Ruppell, which has a high reputation in Germany. The results are recorded below:—

TABLE II.

Experimental animal.	Treatment.	Result.
A, 3 lb. 10 oz.	8 c.c. of B. W. and Co.'s ulcerative endocarditis serum 4 hrs. after injection of streptococcus.	Death within 40 hrs.
B, 3 lb. 14 oz.	8 c.c. of B. W. and Co.'s polyvalent antistreptococcal serum 4 hrs. and again 23 hrs. after injection of streptococcus.	,, ,, 40 hrs.
C, 3 lb. 10 oz.	8 c.c. of Höchst serum 4½ hrs. and 4 c.c. of the same 46 hrs. after injection of streptococcus.	,, ,, 4 days.
D, 3 lb. 6 oz.	7 c.c. of Höchst serum 4¾ hrs. and 8 c.c. of the same 23 hrs. after injection of streptococcus.	,, ,, 40 hrs.
E, 3 lb. 6 oz.	7½ c.c. of P. D. and Co.'s polyvalent antistreptococcal serum 4½ hrs. after injection of streptococcus.	,, after 26 hrs.
F, 4 lb. 6 oz.	7½ c.c. of the same 4 hrs. and 7 c.c. 23 hrs. after injection of streptococcus.	,, ,, 25 hrs.
1st control, 3 lb. 8 oz.	7½ c.c. heated normal horse serum 4¾ hrs. after injection of streptococcus.	,, ,, 70 hrs.
2nd control, 3 lb. 8 oz.	8 c.c. of the same 5 hrs., 24 hrs., and 46 hours after injection of streptococcus.	,, ,, 5 days.
3rd control, 4 lb.	No treatment.	,, within 40 hrs.

In this series of experiments only one of the commercial sera, that of Höchst, showed any protective action, but it was not a marked one. For this reason it was selected for a further experiment in which the effect of smaller doses, repeated more frequently, was tried. It was compared with the fresh serum of a horse which subsequently to prolonged treatment with a variety of strains of streptococcus was immunised against the homologous streptococcus. To this end it received injections of 10 c.c., 25 c.c., and 50 c.c. of cultures similar to those used to inject the rabbits in these experiments: they were given subcutaneously at intervals of 7 to 10 days, and the serum tested was collected a month after these special injections had been commenced.

TABLE III.

Experimental animal.	Treatment.	Result.
A, 3 lb. 4 oz.	Polyvalent and "homologous serum" B. W. and Co. 4 c.c. three hours after injection of streptococcus; 2 c.c. and 2 c.c. subcutaneously 25 hrs. after; 2 c.c. 35 hrs. after; 1 c.c. 48 hrs. after.	Death after 53 hrs.
B, 3 lb. 2 oz.	Of the same 8 c.c. 3½ hrs. after injection of streptococcus; 8 c.c. more and 1½ c.c. Höchst* serum 23 hrs. after; 8 c.c. again 34 hrs. after; 8 c.c. again 48 hrs. after; 4 c.c. again 54 hrs. after; 4 c.c. again 74 hrs. after.	,, within 4 days.
C, 3 lb. 10 oz.	4 c.c. of Höchst serum 3½ hrs. after injection of streptococcus; 4 c.c. of the same 25 hrs. after.	,, after 32 hrs.
D, 3 lb. 6 oz.	4 c.c. of the same 3¼ hrs. after injection of streptococcus; 2 c.c. after 24 hrs.; 2½ c.c. after 34 hrs.; 2 c.c. after 47 hrs.; 2½ c.c. after 55 hrs.	,, within 4 days.
1st control, 3 lb. 12 oz.	7 c.c. of heated normal horse serum after 3¾ hrs.; 7 c.c., 25 hrs.; 7 c.c., 35 hrs.; 6½ c.c., 47 hrs.; 4 c.c. subcutaneously, 55 hrs.; 4 c.c., 74 hrs.; 8 c.c., 96 hrs.	,, ,, 6 days.
2nd control.	No treatment.	,, after 26 hrs.

* This small quantity of Höchst serum was given by mistake in this experiment.

Here again it was found that the Höchst serum had a slight beneficial effect, as had also the serum from the horse previously injected with the "homologous" strain. The chief fact that seems to emerge from these experiments is that infections of the rabbit with this highly pathogenic strain of streptococcus are completely or to a large extent unaffected by the administration of some of the most reputed antistreptococcal sera.

In criticism it might have been urged that this was a rare strain of streptococcus different from any with which the horses yielding these sera had been inoculated; but it is not possible to maintain such a criticism, since the results with rabbits B and C in Table I. are not sensibly inferior to those with A and B in Table III., and the latter were treated with the serum of the same horse as the former after the horse had received repeated injections of the homologous streptococcus. Another explanation must be found, and this might be claimed in the very large dose of streptococcus with which the rabbits were injected. But neither is this a satisfactory explanation; for if the injection of streptococcus was a large one, so also were the doses of serum, corresponding as they did to 100 c.c.—500 c.c. for a human adult, and they were administered soon after the animal had been infected. Further, the infecting dose was certainly not so massive as to produce an absolutely intractable infection, for the life of the animal could always be considerably protracted by the help of normal horse serum. To me the most probable explanation seems to be that against this type of streptococcus no production of immune antibodies takes place. In support of this suggestion the three following experiments showing how difficult it was to immunise a rabbit against it may be quoted. It was found that 5 c.c. of a culture, in 20 per cent. horse serum bouillon, of the original strain (P.M. 8488) killed a rabbit, but that a 1 c.c. dose did not.

Rabbit A, 7 lb. 4 oz. An emulsion in normal salt solution of an old agar sloped culture which had completely dried up was injected on April 4th. As the animal seemed to be quite unaffected a second injection consisting of a similar emulsion of two dried-up cultures, one of them from a passage strain of this streptococcus, was administered subcutaneously on the 9th. The rabbit died within 24 hours; its blood was completely laked and had in film the appearance of an abundant culture of streptococcus in a fluid medium.

Rabbit B, 5 lb. 10 oz. June 11th: 2 c.c. of a culture of the original strain in 70 per cent. rabbits' serum bouillon; the rabbit remained well. June 23rd: 6 c.c. of a culture of the original strain in 30 per cent. horse serum bouillon. June 26th: Died with post-mortem appearances similar to A.†

Rabbit C, 5 lb. 2 oz. June 11th: 3¾ c.c. of a culture of the original strain in 70 per cent. rabbits' serum bouillon; the rabbit remained well. June 22nd: 3 c.c. of a culture of the original strain in 30 per cent. horse serum bouillon. June 24th: Died with post-mortem appearances similar to A.†

In looking for corroboration or explanation of these results in the literature with regard to streptococci it is best to examine only those papers which deal with the different methods of preparing antistreptococcal sera, the results obtained from their use in animal experiment, and the study of the factors underlying immunity to streptococci. Those papers which discuss the results obtained clinically with antistreptococcal sera have no certain bearing on this question since no criterion of the virulence of streptococci pathogenic for man has yet gained general acceptance. The death of a patient from whose blood a streptococcus has been isolated does not necessarily indicate a special degree of virulence in that streptococcus. This question has been more fully discussed in another paper (McLeod[1]).

When the serum therapy of streptococcus infections was first launched those who promoted it fell into two camps. On the one hand there were the authors like Marmorek[2,3] and Aronson,[4] who, assuming the unity of pathogenic streptococci, considered that all that was necessary in order to obtain a good serum was to raise any given strain of streptococcus to so high a degree of virulence, by repeated passages through laboratory animals, that it should be capable of producing a marked reaction in the horse and therefore a copious production of antibodies. They claimed that such sera were active against different varieties of streptococci, and that they had the virtue of lending themselves to tests of efficiency on laboratory animals. On the other hand, Moser,[5] Menzer,[6] and Tavel,[7] depending partly on an observation of the last named that large doses of Marmorek's hyper-virulent cultures could be injected to a cancerous area in a woman's womb without any effect, said that all this testing on laboratory animals was past the point, that reliable sera could only be obtained by injecting horses with as many different strains from man as was possible, and that, since most of these strains were slightly pathogenic to animals and the sera could not therefore be tested by the method of animal experiment, the proof of the efficacy of a serum must depend on the collection of numerous data as to its clinical value. Later Aronson[8] modified his attitude so far as to inoculate his horses with numerous human strains as well as with his passage strains, since he had observed that an animal might still react to the former when fully immunised to the latter.

The next innovation in serum production came from Meyer and Ruppell.[9] These authors tried to combine the advantages of both methods described above. By a special method of cultivation they were able to obtain human cultures virulent for laboratory animals and to maintain the virulence of these strains so as to be able to test the value in animal experiments of their antisera. They found it necessary, however, to immunise their horses first with animal passage strains in order to enable them to support their special cultures from man. As Aronson[10] points out, this is tantamount to an admission that you can immunise against human cultures with passage strains.

Aronson,[11] however, claims that his monovalent serum obtained with a passage strain is superior to Meyer and Ruppell's serum even against streptococci isolated direct from man. Marxer,[12] on the other hand, found that a monovalent serum obtained directly with a human strain pathogenic to animals was effective equally in animal experiment against passage strains, human strains, and strains obtained from horses with glanders. Another point of view is that of Weil,[13] who claims that the antisera of Aronson and others contain only immune body, which is directed against a special type of streptococcus, the passage type, and that they have no effect on most streptococci isolated from man. To prove this he submits experiments in which the bacteriotropine of these sera for passage strains is removed by contact with emulsions of streptococci from cultures of such strains, but not by similar emulsions of strains which have not undergone passage.

Heimann[14] expresses a somewhat similar opinion. He says that Aronson's serum protects from Meyer and Ruppell's passage strain of streptococcus and vice versâ, but that neither protects from strains isolated directly from man. Sommerfeld[15] confirms Aronson's result that the A serum is active against various strains of streptococci, but he subjects all these strains to repeated passage before testing them. This invalidates his conclusion.

Simon[16] ranges himself with Weil and Heimann. He obtained monovalent immune sera by injecting rabbits, and found that sera obtained with highly virulent passage strains protected only against those strains, but not against direct human strains; further, he found that it was very difficult to get efficient immune sera by injection of human strains. The most interesting of his statements is that it is possible to raise the virulence of a streptococcus by passage without changing its individuality, and that after several passages the streptococcus when used for immunising a rabbit will produce relatively powerful protective sera against the direct human strain from which it was derived. He also claims to demonstrate a point at which the human strain becomes converted to a passage strain, but in view of the varying effect of the strain employed on the control animals it is doubtful whether his experimental proof of this point is adequate.

Lastly, one more aspect of this subject is broached by Zangemeister.[17,18] This author, while admitting the efficacy of Aronson's serum in combating infections of mice with various streptococci, considers that there is no proof in this of its value in human disease, and in support of this opinion he quotes experiments in which the serum failed to protect monkeys, and other experiments in which he failed to produce any beneficial effect by administering prophylactic doses of Aronson's serum to patients for whom he feared a peritoneal infection subsequently to the removal of an infected carcinoma of the uterus. He recommends for this reason the serum of the monkey or of men convalescent from streptococcal infections. In reply Aronson[19] quotes experiments to show that the antistreptococcal sera obtained by injection of a large variety of animals, including monkeys, were all about equally useful in protecting monkeys with the exception of two monkey sera which did not protect mice. He further states that Zangemeister's prophylactic experiment on man is not a reasonable one, since the effect of antistreptococcal serum depends on the coöperation of the leucocytes which could not be obtained in a cancerous subject with deranged leucocytic activity. This is scarcely a convincing argument, since a deranged leucocytic activity in this sense in cancer is only an assumption, and people who are infected with streptococci are perhaps more liable to have their leucocytic systems deranged by the toxæmia from which they suffer.

---

† This strain of streptococcus appeared to grow better in the second medium used in these experiments than in the first.

The data obtained by various authors with regard to the efficiency of antistreptococcal sera are given in Table IV.

hæmolytic toxin of the streptococcus, streptolysin, is formed in animals injected with it, and McLeod and McNee[35] have shown that the hæmolytic toxin and general toxin of the streptococcus are closely allied and possibly identical.

There are, however, three types of antibody which have been shown to exist in these sera. Two of these are unimportant. An amboceptor capable of absorbing complement was demonstrated by Besredka[21] in his own antistreptococcal serum; he could not find it in that of Aronson, but he admitted that there was no definite relationship between its amount and the protective power of a serum. Agglutinins for streptococci have been obtained by a number of authors, notably Neufeld[36] and Kerner,[37] and have been used for aiding classification. Little is known as to their significance in streptococcal immunity. The third antibody, to which by general consent the chief rôle in the protective action of antistreptococcal serum is ascribed, is an immune opsonin or bacteriotropin. This immune body was first fully described by Neufeld and Rimpau,[38] who suggested that its function was to neutralise those amboceptors to which the virulence of a streptococcus was due; it was, they considered, owing to the absence of such amboceptors in avirulent strains that these were useless for obtaining actively bacteriotropic sera.

TABLE IV.

Author.	Sera tested.	Prophylactic value.	Curative value.
A. Marmorek.[2]	Serum of horse treated with hypervirulent passage cultures.	0·2 c.c. protected against 10 m.l.d. (rabbit).	1 c.c. protected 3 hrs. and 5 c.c. 5 hrs. after an injection of 10 m.l.d., but not later, except in the case of moderately virulent streptococci (rabbit).
F. Meyer.[20]	No details.	Large doses had occasional preventive action, but not against virulent strains.	—
H. Aronson.[4]	Serum of horse treated with hypervirulent passage strains.	0·0005 c.c. protected against 10 m.l.d. (mice). Rabbits required more proportionally to their weight, 0·5 c.c.–1·0 c.c.	0·05 c.c. protected from 3 till 24 hrs. after injection of 10 m.l.d. (mice). 5–10 c.c. usually cured rabbits 6 hrs. after infection.
Besredka.[21]	Serum of horse treated with intravenous injections of emulsions of serum agar cultures.	—	0·001 c.c. of serum protected against 10 m.l.d. 18–24 hrs. after infection. 1·5 c.c.–2 c.c. serum protected against more than 100 m.l.d. 2 hrs. after infection (rabbit).
Ruppell.[22]	Serum of horse treated with hypervirulent passage cultures.	0·0002 c.c. protected against 10 m.l.d. (mouse). 1·0 c.c. protected against 10 m.l.d. (rabbit).	1 c.c. of serum protected against 2 m.l.d. (rabbit) 6 hrs. after infection. Ruppell and Meyer[9] admit that they meet strains from time to time against which their serum is ineffective.
Weaver and Tunnicliffe.[23]	Parke, Davis and Co.; Aronson; Institut Pasteur.	Protection only obtained when injection proceeded that of culture by 4 hrs.	Protection was only obtained with difficulty and when the serum was administered within a few hours of the injection of a small dose of culture (guinea-pig).
Chiarolanza.[24]	Aronson; Tavel.	—	Where cultures were injected to the rabbit's peritoneum these sera never protected against virulent strains of streptococci, but frequently against ones of lesser virulence.
Von Lingelsheim.[25]	Schering; Höchst.	—	0·25 c.c. of serum protected against 100 m.l.d. up to 6–8 hrs., but not against greater amounts or after a longer time (mice).

Factors Underlying Immunity to Streptococci.

It is generally accepted, at the present day, that in the sera of animals immunised with cultures of streptococci, filtrates of these cultures, or with streptococcal aggressins certain antibodies do not occur. Thus Ruediger,[26] Lomonaco,[27] Weil,[28] and Reichstein[29] have demonstrated the absence of bactericidal action in antistreptococcal serum and in the blood of infected animals, since, as a matter of fact, virulent streptococci often grow well in either. Weil[30] showed that the injection to guinea-pigs and mice of filtered peritoneal exudates of animals which had been subjected to a streptococcal infection did not lead to the production of any immunity. Besredka,[31] Tchitchikine,[32] McLeod,[33] and Braun[34] have shown that no antitoxin to the

With regard to one point at least in this connexion there is marked unanimity amongst the various authors—namely, that cultures of streptococci killed by heat are of no value for immunising. Neufeld[36] alone claims for them some activity, since he always starts immunising with large quantities of culture killed by heat before proceeding to inject living cultures. Bacteriotropin does not appear to be formed in any sensible amount except when the living bacteria are engaged in a struggle to maintain their footing in the animal body, so much so that Schenk[39] found that the more ill an animal was at the moment of drawing blood the greater the protective power of its serum was likely to be. Weaver and Tunnicliffe[40] show that the opsonic power of the serum of an animal injected with streptococci killed by suspension in 25 per cent. galactose was raised, and that simultaneously its resistance to infection was increased, whereas neither the one nor the other was changed by injection of streptococci killed by heat. Weil[30] states that immunity is only conferred on mice and guinea-pigs by the presence of live streptococci in their body.

Discussion.

Although so many of the experiments performed with a view to elucidating this subject appear to have yielded contradictory results there is yet a general trend of evidence which can afford considerable help in determining the practical value of antistreptococcal sera. The value of this remedy for streptococcal infections in mice with homologous streptococci has been proved beyond all question, but the efficiency of these sera for the rabbit is a long way behind that for the mouse apart altogether from the difference in weight of the two animals, and if the dose necessary for man should only increase in the ratio of his weight to that of the rabbit, the prospect of successful treatment would depend on the immediate administration and frequent repetition of huge doses, costing from £2 to £6, and even this calculation is based on the assumption that the serum employed will react specifically with the strain of streptococcus in question. How far is this assumption justified?

The value of any serum administered to a patient must depend, apparently, on the amount of immune opsonin conveyed to him for the strain with which he is infected, but there are several reasons for doubting whether the amount of this body conveyed even in large doses of antistreptococcal serum is ever sufficient seriously to influence the course of a streptococcal infection. In the first place, there is some evidence indicating that up to a certain point there is a specific opsonin for each strain of streptococcus. Thus Meakins[41] found on examining the sera of patients suffering from various streptococcal infections that their opsonic action was always decidedly raised for the streptococcus with which they were infected, but very little or not at all for other streptococci, whether these were isolated from similar morbid processes or not. But even if we do not adopt this extreme attitude we find so many authors agreeing that the sera obtained with hypervirulent passage strains protect only against such strains and not against strains of direct human origin (Meyer and Ruppell,[9] Simon,[16] Heimann,[14] Weil[13]), that we cannot reasonably expect satisfactory results from such sera in human therapeutics. Then, on the other hand, a number of authors (Aronson,[4] Simon[16]) point out that the animals from which sera are obtained react very slightly to streptococci derived from human sources and therefore yield little antibody. Even Meyer and Rupell,[9] who by a special method of culture obtained direct human strains which were highly pathogenic to animals, and who treated their horses with a large variety of these as well as with passage strains, admit that they occasionally meet fresh strains from which they cannot protect laboratory animals with their serum.

Heynemann and Barth[42] could not find any abundance of opsonins or any other protective antibodies in various antistreptococcal sera which they examined by means of test-tube experiments, nor were their results in treating puerperal septicæmia with 100 c.c. doses at all reassuring. In fact, the only theoretical ground in this connexion which appears to exist for persisting in the serum therapy of streptococcal infections is contained in the work of Simon,[16] who shows that animal passage increases the virulence and immunising power of strains isolated from man without immediately changing their characteristics to those of the typical passage strains. According to this conception, what is required for successful serum therapy is that the serum used should have been prepared with a strain of streptococci closely allied to that causing the infection and having undergone a sufficient number of passages to raise its virulence without changing its other characteristics. Suppose, however, that it is granted that there is available for any given streptococcal infection an animal serum containing abundant opsonin, it does not follow that the administration of any ordinary doses of such serum will be effective. If we divide streptococcal infections into three groups, (*a*) slight, (*b*) severe, and (*c*) very severe, we find that in group (*a*) recovery is spontaneous. In (*b*), in which there is a severe infection with recovery in a considerable percentage of cases, the very best conditions for stimulation of opsonin formation in the patient's own body are present, since Schenk[39] has shown that in streptococcal infections of the rabbit the protective power of the serum is greatest during the period when the animal is most ill. It is therefore very doubtful whether the addition of a relatively small amount of extraneous opsonin in the form of antistreptococcal serum would be of much help. Of course, in the case of a patient who did not form any opsonin in response to the stimulus of streptococcal infection the position would be different, but apart from cases of severe toxæmia it remains to be proved that such patients exist. In (*c*), the very severe infection, the patient is suffering from a severe toxæmia which is causing a partial or complete paralysis of his leucocytic system; it is not, therefore, opsonin which he requires but antitoxin, and by general consent the various antistreptococcal sera do not contain any antitoxin. Further, my own work, recorded above, shows that there appears to be no development of immunity against strains of streptococci which are very virulent for the rabbit and which produce a marked toxæmia in the bodies of the infected rabbits. In this connexion it is interesting to note the results of Strouse,[43] who never succeeded in obtaining immune opsonins for highly virulent pneumococci in the sera of animals which had been injected with them, nor yet in the sera (post critical) of the patients from whose sputum or blood they had been recovered. He quotes Boettcher in support of this result. Before leaving this subject it should be pointed out that even in the group (*b*) the rôle of streptococcal toxin may be considerable, since a number of experiments on the rabbit have shown that the animals sometimes die 10–20 days after an injection of streptococci, although their blood does not appear (culture) to contain any streptococci at the time of their death. Weil[13] attributes these deaths to the remote effects of streptococcal toxin.

The conclusions which I feel inclined to draw from the literature of this subject and from my own work upon it are the following:—

1. That a certain type of streptococcus exists,

very virulent for rabbits and capable to a peculiar degree of producing toxin in the body of an infected animal, against which rabbits cannot be readily immunised, and that the serum of a horse treated with injections of these streptococci is not capable even in large doses of conferring passive immunity on the rabbit.

2. That a careful perusal of the literature with regard to antistreptococcal sera leads to the opinion that none of the sera available is likely to afford a supply of immune opsonin at once adequate in amount and sufficiently adapted to the strain of streptococcus involved markedly to alter the course of streptococcal infection in man.

3. That in the treatment of severe streptococcal infections normal heated horse serum, which has been proved slightly superior in the experiments recorded in this paper, and which would in any case be cheaper and more easily preserved, might, if administered in large doses, be substituted with advantage for commercial antistreptococcal serum.

4. That experimental work on the therapy of streptococcal infections which aims at finding some artificial antibody to streptococcal toxin is much more likely to be fruitful than any further efforts to amend and improve the methods of immunising horses to this type of bacteria.

I desire to express my hearty thanks to Dr. William Hunter, in whose laboratory this work was carried on; and also to Messrs. Meister, Lucius, and Brüning, Höchst Farbwerken, Messrs. Burroughs, Wellcome, and Co., and Messrs. Parke, Davis, and Co. for specimens of antistreptococcal serum with which they have kindly supplied me. I am specially grateful to Dr. H. H. Dale, of the Wellcome Physiological Research Laboratory, and to some members of his staff for the opportunity which they afforded me in carrying out one part of this investigation.

THE OPERATION OF SCLERO-CORNEAL TREPHINING,

CONSIDERED IN RELATION TO THE PRINCIPLES WHICH SHOULD GUIDE AN OPERATOR IN THE PERFORMANCE OF A SCLERECTOMY.[1]

BY R. H. ELLIOT, M.D. LOND., F.R.C.S. ENG.,
LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE.

THE essential feature of all forms of sclerectomy is the removal of a portion of the outer tunic of the eye, and the establishment thereby of continuous drainage from the interior of the globe into the subconjunctival space. An effort has been made by some ophthalmologists to draw a distinction between the fistulous scars so obtained and the "true filtering scars" which they claim are produced by methods in which the removal of a piece of the investing tunic is avoided. It is obvious that if it could be shown that a spongy fistula-free scar is a possibility, it would be correct to draw a sharp distinction between such wounds and those which include one or more fistulæ in their area. Unfortunately, however, no such evidence exists, and on the contrary all that we know of scar tissue is opposed to the view that it will under any circumstances remain loose, open, and permeable to fluid. It may be that a wound may include not one large fistula, but a number of tiny ones instead; this, however, is quite a different thing from what has ordinarily been understood by those who apply a limited significance to the term "filtering scar." In the meantime the majority of ophthalmologists have apparently decided, a little loosely perhaps, to consider the terms "filtering" and "fistulous" as synonymous. It is proposed in this paper to conform to this usage, and the more readily so since the writer believes that in the treatment of glaucoma *we fail in our purpose if we fail to establish fistulisation.*

This statement leads one to turn aside for a moment to consider the results which have been obtained by iridectomy in the treatment of glaucoma. It has often been urged that iridectomy alone will cure cases of glaucoma, and that in such eyes the smooth appearance of the conjunctiva negatives the idea that subconjunctival filtration is taking place. Such a view is fallacious; it is quite easy in a very large proportion of these cases to demonstrate well-marked subconjunctival œdema by gentle local pressure with a spud. It is probable that the operation of iridectomy is only of value when it leads either to the establishment of a permanent filtration, or at least of one which persists long enough to allow of the re-establishment of normal conditions within the eye. The argument that the uniform grey appearance of such scars shows that they represent filtering as distinguished from fistulous conditions cannot be seriously entertained in the absence of confirmatory anatomical evidence. It is doubtful if such will ever be forthcoming.

We are thus led to the key of the whole position, which is contained in the statement that in the operative treatment of glaucoma we must aim at the establishment of a permanent subconjunctival fistulisation of the eye. Within this broad assertion many minor considerations are included—e.g., that every possible means must be taken to assure the safety of the eye both at the time of operation and subsequently, and that the degree of fistulisation produced must bear some definite relationship to the needs of the particular case. It is proposed to consider these matters now in connexion with the technique of sclero-corneal trephining.

---

[1] This paper was written by request to be read at the International Congress of Ophthalmology at St. Petersburg, August, 1914. Owing to the outbreak of the war the Congress was not held, and is postponed *sine die.*

The Operative Conditions Necessary to Establish Permanent Filtration.

These are (1) asepsis of the wound; (2) the formation of a suitable channel of sufficient size in the investing tunic of the eye, the size being capable of graduation according to the needs of the case; and (3) avoidance of the entanglement of uveal tissue in the wound, either at the time of operation or later.

(1) *Asepsis.*—It is a primary condition of success that the fistulous channel should from the first be kept aseptic and bathed in the isotonic, unirritating aqueous fluid. The most scrupulous antiseptic and aseptic technique is therefore called for, and the use of large flaps is an obvious indication. Any failure in our asepsis will promote the formation of proliferative tissue in the trephine hole, and thereby predispose to blockage. The proliferative tissue may arise from the surface or from the depth of the wound, and possibly also from the sides of the tunnel. One sees cases in which it seems likely that the source of the sepsis may be present in the eye before operation, and in which the prognosis will therefore be a poor one, whatever care we may take.

(2) *The channel.*—Experience has shown how necessary it is that we should be able to cut a channel of the size we require, making it larger or smaller according to the needs of the case. An eye suffering from a chronic non-congestive glaucoma will be relieved by a very small aperture, especially if the rise of tension is not an excessive one, whilst another, which has long been subject to attacks of a congestive type, will demand a free aperture if the drainage is to be permanently maintained.

A 2 mm. trephine should, I think, always be used, and the amount of disc cut off should be regulated according to the needs of the case. In every case the corneal edge of the trephine should be made to cut its way through first, so as to leave the hinge of the disc on the scleral side. If it is desired to remove the whole disc the tilting of the instrument should be slight, and just sufficient to ensure the leaving of a tiny strand of uncut scleral tissue; if, on the other hand, we desire to remove a half or less of the disc, it is advisable still farther to incline the instrument so that a larger hinge may be left; this is merely a question of the angle that the trephine edge makes with the tunic of the eye, and depends on the tilt that we give the upper end of the instrument towards the patient's feet. The disc is pushed up into the wound by the pressure of the iris behind it, and it can be easily seized with iris forceps and as much of it cut off as we wish. In so doing the cut with the scissors should be at right angles to the plane of the portion excised, so as to avoid the making of a slanting wound; the latter is to be avoided, since the sectional area of the channel made should obviously be kept the same right throughout, in order to gain a maximum of effect with a minimum of weakening of the supporting coat of the globe. The objection to what would appear to be the more obvious plan of reducing the size of the trephine blade is that it is not possible to work with iris forceps and scissors in any aperture of less size than one of 2 mm. We are therefore well advised to make our aperture large enough in the first instance, in order that we may be in a position to deal with iris trouble should it arise.

It is most desirable to operate in such a way as to *ensure the production of fistulisation*, and it is submitted that this end is probably best served by making a clean-cut channel at right angles to the surfaces of the tunic. Any attempt at tunnelling through the sclera, such as is involved in the making of slanting incisions, will militate against the certainty with which permanent fistulisation can be secured. It is most necessary to emphasise the fact that the greatest difficulty in operating for glaucoma by means of any form of sclerectomy is the permanent maintenance of the filtering channel. Beside this, and in comparison with it, all other difficulties fade into insignificance. I feel sure that this will be the verdict of all surgeons with large operative experience. It is not disputed that there are many other difficulties and dangers which we have to meet, and they must be taken seriously into account, but it is of vital interest that we should not lose our sense of proportion, or our results will suffer thereby.

(3) *The avoidance of the entanglement of uveal tissue in the wound.*—The investigation of globes, which have been removed after the failure of trephine operations, has confirmed the correctness of the view, long ago put forward from Madras, that the impaction of uveal tissue in the trephine hole constitutes a grave complication of any case in which it occurs. In the first place it tends to block the hole mechanically, and in the second it is liable to lead to a later obstruction, owing to the proliferation of inflammatory connective tissue. On the other hand, experience has most conclusively shown that, since we have adopted the more anterior position for our trephining, we have very materially lessened those dangers of the procedure which were incidental to complications resulting from the impaction of uveal tissue in the wound.

It is first necessary to look at the question from the anatomical standpoint. Rochon-Duvigneaud has shown that the measurement of the interval between the angle of the anterior chamber, on the one hand, and the transparent edge of the cornea on the other, is 2·25 mm. in the vertical meridian above the cornea. To this space, available for the implantation of the trephine, we can add at least 1 mm. by splitting the cornea. On the other hand, we have to remember that adhesions between the iris base and the periphery of the cornea, and the dragging forward of the ciliary body, both of which are met with in long-standing cases, may seriously lessen the area at our disposal. There is a farther point, which is of considerable importance: if the trephine hole is placed far back its internal opening lies on practically the same plane as that of the iris, whilst the more anteriorly the trephining is made the greater is the antero-posterior distance separating the two structures. Now, when a chamber refills after operation, the natural tendency of the iris is to fall back into its own plane, and thus to be carried as far as possible from any opening in the corneo-sclera, always provided that this opening lies on a plane anterior to that of the iris, and that the latter membrane is not itself pushed forwards by structures lying behind it—e.g., the lens or vitreous body. These anatomical arrangements show that, apart from any pathological considerations arising out of the presence of uveal adhesions, there is a distinct element of safety in making the trephine hole far forward. The position may be thus summed up: *It is essential to place the trephine hole as far from the angle of the chamber as possible, in order to avoid the impaction of uveal tissue in its channel.*

The technique I have advocated makes this condition easy of fulfilment. The trephined disc, hinged on its scleral side, can be dealt with according to the exigencies of the individual situation. Whether we remove nearly the whole of it, or less than a third of it, the fistula formed lies on the corneal side of the wound, and all the tissue left remains interposed between the angle of the chamber and the inner opening of the fistula, thus removing the latter as far as possible from the neighbourhood from which danger may be feared.

Whilst separating the disc we should at the same time deal with the iris. It is an easy matter to include both iris and disc in one grip of the forceps, and to divide both together with a single snip of the scissors, thus performing the iridectomy with the same cut that severs the hinge. The great advantage of this is that our grip of the disc steadies the eye, and effectively prevents even a troublesome patient from rotating it until after the portion of iris has been removed. We are thus enabled to avoid all risk of the uveal tissue being dragged into, and becoming impacted in, the trephine hole. It cannot be too strongly insisted on that all drag on the iris should be avoided during the manipulations in the course of this operation.

The Protection of the Fistulous Track after Operation.

This is best accomplished on the operation table by the adoption of a correct technique in dealing with the flap. The assertion has recently been made by critics of the operation of trephining that the filtering scar produced by this method is of the vesicular type, and that the area of filtration is limited to that immediately surrounding the wound. If one starts from such a basis it is not difficult to show that trephining is a very faulty method. Fortunately, however, it is within the power of anyone who will adopt a correct technique to prove for himself that the above assumptions are incorrect, that the prominent vesicular scar is a product of faulty workmanship, and that a well-performed operation leads to the establishment of an area of filtration as extensive as that of the subconjunctival space itself. What, then, are the points to attend to in order to avoid the defects we have been discussing? The answer lies in the preparation of the covering conjunctival flap. The flap must be (1) correct in form, (2) large in size, and (3) correct in the method of its preparation.

(1) *The form of the flap.*—I have for years insisted on the necessity of making the conjunctival incision run concentric with the limbus and at some distance from the latter throughout its extent. The object of this, as is well known, is to render the whole of the subconjunctival space available for filtration. If one examines a correctly trephined eye months or years after the operation one finds that the pitting of the conjunctiva, obtained by probe pressure, is best marked near the trephine hole, less so at each side, and perhaps indetectable below the cornea. If, however, the globe is now well massaged, or if the filtration is exceptionally free to start with, the pitting can be obtained without difficulty, even in the quadrant farthest away from the hole.

(2) *The size of the flap.*—It is probably unnecessary to insist any further on the need for making the flap large, since this is now so widely recognised by surgeons everywhere. Large flaps do not produce astigmatism, and they are a safeguard against wound infection and a factor favourable to the widespread diffusion of the filtering fluid. Large flaps also tend to lie well in place and so help us to avoid the necessity for the use of sutures; it must be obvious that the avoidance of sutures makes the procedure shorter and safer.

(3) *The correct dissection of the flap.*—It is unnecessary and therefore unsurgical, to dissect up the whole area included in the flap; moreover, by so doing we rob the flap of the check-ligament-like action of the connective tissue at the angles of the wound. If we leave the tissue intact the detached conjunctiva tends to spring back into place the moment it is released from the downward pull, whilst if we dissect up the margins of our wound we find that at the close of the operation the flap falls limp and inert over the eye like a loose apron. We should for this reason carry our dissection down to the limbus over the central area of the wound alone. This does not prevent us from exposing the area we require for trephining, whilst it helps very materially to make the finished flap lie in good position. In the upper part of the dissection it is not necessary to take up anything but loose conjunctiva, but as the limbus is approached we should work down to the sclera, and lay the latter *bare* in the last few millimetres of the wound. At the same time the breadth of the area dissected should contract as the cornea is approached, so that when the latter is reached we only expose just such a breadth of it as we mean to split, and very little more. The limbus must next be clearly defined, and the adjacent sclera carefully cleared of any tags of connective tissue. Lastly, the cornea is to be split. The examination by Mr. Sydney Stephenson of eyes in which trephining had failed, showed clearly that the cornea had really been split, and that the flap made included, not merely the anterior epithelium and Bowman's membrane, but also some of the superficial layers of the cornea, which could be traced for a long distance in the sections and which could be seen to be separated from the deeper layers. Recently Captain C. H. Reinhold, I.M.S., has sent home from India some eyes in which he split the cornea in the post-mortem room; these have kindly been examined by Mr. J. Fison, and have conclusively confirmed the deductions drawn by Mr. Stephenson from his more difficult material.

If the technique I have advocated is closely followed the surgeon will obtain thick-based flaps which will have small tendency to form vesicular scars, but which, on the contrary, will provide a wide and even area of filtration. Nor is there any reason to fear that the corneal portion of the flap will fail to allow of filtration or that it will tend to be vesicular in type. If such things do happen it is because the technique of our operation has been faulty.

Post-operative Iritis.

At least three different conditions appear to have been dealt with, and I think confused, by some recent writers when discussing post-operative iritis—viz., (1) the commonly occurring post-operative complication, usually called "quiet iritis," which is familiar to every surgeon who trephines; (2) an exacerbation of, or may be merely a continuance of, an acute or subacute condition which existed prior to the operation; and (3) a true septic condition of the wound, due to an accidental contamination at or after operation. It is important to keep these three classes of cases absolutely distinct in one's notes and in one's mind.

1. *The quiet iritis.*—The act of trephining alters the relationships of the parts which border on or project into the anterior chamber. This chamber is, for a time at least, practically empty, with the consequence that the iris lies in direct contact with the lens capsule, the posterior chamber being temporarily reduced to a potential cavity; at the same moment the long-continued mydriasis has given place to a state of more or less marked myosis; it follows, therefore, that we have to hand the very conditions which render the formation of posterior synechiæ most easy. Again, the fluid secreted after the operation is probably of such a nature as to render the deposition of fibrin from it more liable to occur, and this without premising an access of inflammatory action. It has been assumed that this form of iritis is characteristic of trephine operations. I am confident that it is far from uncommon after other procedures designed for the relief of tension, inclusive of simple iridectomy. The practical lesson to be learnt is that atropine should be freely exhibited from the second or third day after operation onward until all tendency to the formation of synechiæ has ceased. If this be done "quiet iritis" can be reduced to the rank of an inconvenience; otherwise it is a serious danger.

2. *A continuation of, or an exacerbation of, an acute or subacute condition which existed prior to the operation.*—A careful survey of such cases suggests the idea that we have to do with a septic action which was in existence before the operation, and which is, for the present at least, beyond the operator's control. It is probable that toxicity, possibly in many forms, is playing no unimportant part in the pathogenesis of some at least of the conditions which we now, for convenience' sake, are content to group together under the one label of "glaucoma," guided, as we are, by the one central and dominating feature of a rise in intraocular tension.

3. *A septic contamination of the eye at the time of operation* calls for little comment here. With ordinary care and the use of a large flap it should be a very rare event indeed.

Some surgeons (amongst others, Parker of Detroit, Hill Griffith of Manchester, and MacCallan of Egypt) advocate the performance of a complete iridectomy on the ground that quiet iritis is thereby avoided. My own practice has been to perform a button-hole iridectomy, and to use atropine freely if synechiæ tend to form. There are certain disadvantages which follow the making of a complete iridectomy—viz., (1) blurring of images; (2) dazzling complained of in bright light; and (3) the fact that we are deprived of the power of producing strong myosis, should we require to do so later on.

Of the preventive and curative treatment of those forms of sepsis which may lead to an increase in intra-ocular tension it is too early yet to speak, but there can be little doubt that the laboratory will in time come to the aid of the ophthalmologist in this direction. Meantime we must work on general principles.

Late Infections.

A number of cases of late infection after trephining are now on record, and considerable stress has been laid on the occurrence of this complication. There would seem to be a tendency to forget (1) that during the last four years an enormous number of eyes have been trephined; (2) that the condition for which this operation is undertaken is a very desperate one; (3) that many of the operators are still new to the method; and (4) that the same disaster has overtaken the subjects of other operations for glaucoma—e.g., Lagrange's and Herbert's procedures. Moreover, some of the cases recorded are not above challenge; one cannot fairly class under late infections cases in which inflammation first showed itself very shortly after operation. These should be included either under operation infections or possibly under auto-intoxications. Nor are the cases following injuries to be accepted without considerable reservations. Gifford has pointed out that neither Professor Lagrange nor I have met with one of these late disasters, and has, I think correctly, attributed our immunity to our technique of using "thick flaps." This matter has been already discussed above. Lagrange's experience is a very large one, extending over many years, whilst I am able to speak from over 1000 cases, of which more than 200 have been followed for periods varying up to four years. It is not my intention to attempt to belittle the importance of late infections following sclero-corneal trephining, or to suggest that such an occurrence constitutes the least reflection on a surgeon's methods; but in the case of an operative procedure, which is of so recent an origin as sclerocorneal trephining, it is obvious that we all have still much to learn as to technique, &c.

I would suggest two conditions which may pave the way for the occurrence of late infection. These are: 1. The persistence of a leaking fistulette somewhere along the line of the original conjunctival incision; with this is associated a shallow anterior chamber. The fistulette can be speedily closed by touching the spot with 2 per cent. silver nitrate solution on a swab. 2. The presence of a thin vesicular filtration scar. This latter condition has been very fully discussed already. It only remains to add that we should impress on our patients the risks of injuries or of conjunctival infections, and the need of speedily seeking expert advice in the event of any slight eye symptoms making their appearance.

I wish to say a very few words in conclusion on some features of operative procedure, which should in my opinion be avoided if possible in an endeavour to establish subconjunctival filtration.

1. *Inefficiency.*—My personal experience of sclerotomy is comparatively limited, but the general consensus of opinion seems to be that the end result is too often unsatisfactory, unless a portion of the coat of the eye is definitely removed. It is surely in the interests of both surgeon and patient to avoid the disappointments thus caused.

2. *Dangers.*—It is most important to make an operation for glaucoma as safe as possible and to eliminate all avoidable dangers. (*a*) The introduction of a keratome point into the shallow chamber of a glaucoma patient is, I think, objectionable, and a handicap to any method which requires it. (*b*) The making of a larger opening in the tunic of an eye than that which is required for the purposes of the fistula

about to be established obviously presents distinct disadvantages. (*c*) The necessity for performing the removal of the piece of the tunic (in other words the actual sclerectomy) on an opened eye is widely considered to be a hazardous and anxious procedure. In trephining we perform the actual sclerectomy on an eyeball which to the last moment remains closed and distended with fluid. Moreover, it may be claimed for trephining that, by virtue of the small aperture made, it approaches more nearly to the conditions, and therefore to the implied safety, of a sclerotomy, than does any other form of sclerectomy.

Welbeck-street, W.

ELECTROLYTIC PREVENTION OF LEAD POISONING.

BY KENNETH GOADBY, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.,

SPECIAL MEDICAL REFEREE FOR LONDON FOR INDUSTRIAL POISONING; PATHOLOGIST AND LECTURER ON BACTERIOLOGY, NATIONAL DENTAL HOSPITAL.

IN a paper entitled "The Preventive and Curative Treatment of Industrial Lead Poisoning"[1] Sir Thomas Oliver discusses at length an electrolytic method of eliminating lead from the body, which he described as a "new, or bipolar bath," the method described being the use of four vessels, one for each foot and one for each hand, the two sets of baths holding the positive and negative electrodes respectively, as opposed to the method of a "single bath" in which one electrode, anode or cathode, is placed in the bath, the other or indifferent electrode being applied to the skin by means of a pad moistened with salt solution.

In the paper referred to a claim is made of the efficacy of this method for the treatment of chronic lead poisoning, based upon the supposition that "lead is probably present in the tissues in the form of metallic chloride or other inorganic salt," and that under the influence of the electric current it would be passed outwards and be deposited electrolytically on the aluminium electrodes. It is stated that under the influence of the electrolytic method the blue line present in the gums of persons suffering from lead absorption disappeared, and that lead was demonstrable upon the electrodes in the baths. It was therefore thought of interest to inquire experimentally into the behaviour of lead salts in relation to albuminous substances, and the possibility of the experimental removal of lead from the tissues of lead-poisoned animals.

The bath recommended by Sir Thomas Oliver consists of two arm and leg baths, sufficiently deep to allow immersion of the limb to the elbow or to the knee, the anode being placed in the foot bath and the cathode in the arm bath; the electrodes were of aluminium, and a current of 20 to 40 ma. was used at a voltage of 16. The baths were filled with salt solution. The experiments I have conducted were devised to follow, as far as possible, these conditions, but the current employed was varied from 20 to 100 ma. Blank control experiments were undertaken in every instance. Aluminium electrodes were used in the earlier experiments, but after washing the electrode with HNO_3 and passing H_2S for the detection of lead a black precipitate was obtained of iron sulphide; the aluminium electrodes were therefore abandoned and platinum used. Some trouble was also experienced with both the distilled water and sodium chloride, owing to both containing minute traces of both iron and copper when the ordinary laboratory materials were used; and special care was therefore taken to eliminate this source of error.

Account of experiments.—Six animals were subjected to experiment, four cats and two dogs. Lead nitrate was used, and 0·05 grm. per kg. body weight was inoculated intramuscularly into the muscles of the back and neck. After a variable period, 10 to 20 days, the animals were subjected to electrolysis; the forelegs were immersed to the shoulder in one bath, and the hind legs in another bath of normal saline; the electrodes, platinum soldered into platinum wire with pure gold, were placed in each bath, and a current controlled by a shunt resistance, voltmeter and milliampèremeter passed through. The animals were placed under an anæsthetic during the experiment.

With the first two animals a current of 30 ma. at 20 volts was used. After an hour's passage no deposit of lead was found on either electrode (cathode or anode). Towards the end of the experiment the animal's heart showed signs of great acceleration. This acceleration was much more pronounced when the whole four limbs of the animal were immersed than when only one foreleg and one hind limb of the same side were placed in the bath circuit.

In the third experiment the current used was increased to 100 ma. The heart beats became accelerated after 10 minutes' application of the current, the heart finally ceasing to beat. The current was stopped and artificial respiration and massage to the chest applied. The heart commenced to act again, but was hypersensitive to 30 ma. of current and finally ceased to beat. The electrolysis was continued for 30 minutes after the animal was dead, with a current of 100 ma. The electrodes were subsequently washed with hot 10 per cent. HNO_3 containing a few drops of alcohol, and the washings investigated for the presence of lead. No black precipitate was obtained with sulphuretted hydrogen, or any evidence of the presence of lead.

A fourth experiment with a cat gave exactly similar results, and no lead was obtained from the electrodes even after 1½ hours' exposure on four different occasions.

A dog was inoculated with lead nitrate, 0·05 grm. per kg. body weight being used. At the end of three weeks symptoms of lead paralysis were evident, and the animal was submitted to electrolysis. A current of 50 ma. at 20 volts was used, with normal saline baths free from lead and iron, and platinum electrodes of 300 sq. cm. surface; the time of exposure was one hour. Three baths were given, but the animal died from general lead paralysis. No lead was recovered from the electrodes on either of these occasions.

After death the animal's liver was removed and found to weigh 335 grm. A quantity, 162 grm., was removed and triturated in a mortar, normal saline added, and the whole placed in an electrolytic cell with platinum electrodes and a current of 0·14 ampère passed for 12 hours. The electrodes were then removed and tested for lead by washing in distilled water, boiling with 10 per cent. HNO_3, with a few drops of alcohol. The washings gave no black precipitate on neutralisation with KOH and passing H_2S. The substance was then transferred to a large evaporation basin, strong HNC_3 and potassium chlorate added, and the substance digested till all organic matter had disappeared, evaporated to dryness, incinerated, and the residue taken up in 10 per cent. HNO_3 and the fluid returned to the same cell for electrolysis. The conductivity was found much greater than before, and a considerable extra resistance was necessary to reduce the amperage to 0·14, the same reading as in the undigested liver emulsion. The cell was allowed to act for 12 hours. At the end of this time the anode was coated with a black deposit, which was found to be lead; the cathode was free from lead. The quantity estimated volumetrically was found to be 0·0049 grm. for the whole weight of liver.

Lead was therefore present in the liver, probably as an "albuminate"; it was not acted upon or deposited by the electric current until it had been freed from its organic combination, but when this was accomplished and a suitable electrolyte used a deposit readily took place. A metal adsorbed by albumin is undissociated. There was therefore no experimental evidence to show that lead is ionisable when present in the animal body, either in the incipient or established stage of lead poisoning. The absence of any deposit from the electrolysis of the animal's liver emulsion, subsequently shown to contain lead, as well as the much lower conductivity of the solution, points to little dissociation of lead ions in the body; and as without such dissociation no deposit of the metal is likely to take place this question was submitted to further tests as follows:—

---

[1] THE LANCET, August 23rd, 1913, p. 527.

A 10 per cent. solution of lead nitrate was added to a 5 per cent. solution of egg albumin, the thick curdy precipitate was filtered off and washed with distilled water, and dialysed against distilled water for four weeks. Even at the end of this time traces of lead were found in the dialysis water. Suspended in water no black precipitate was obtained with H_2S, but on addition of HCl or KOH a thick black precipitate was obtained. With Millon's reagent the dialysate also gave red precipitate, as well as the biuret reaction with copper sulphate. The substance thus gave the combined reactions of lead and albumin, but still contained some free lead as shown by the washings.

About 10 grm. of the "lead albuminate" was next treated with 25 c.c. normal horse serum and allowed to stand for 12 days, after which the supernatant clear serum was pipetted off and tested electrolytically as follows. A cell was constructed with an inner and outer vessel; in the outer vessel was placed normal sodium chloride. The inner vessel consisted of a dialysis tube of parchment paper and contained the serum which had been in contact with "lead albuminate." Two platinum electrodes, 5 × 10 cm., were placed in the inner and outer vessels, and a current of 0·1 ampère at 8 volts passed, the apparatus being left all night at the room temperature. The electrodes, which were quite bright, were removed at the end of 14 hours, washed gently in distilled water, and subsequently boiled in 10 per cent. HNO_3, with the addition of a few drops of alcohol, and the fluid tested for lead with negative results.

The serum was then removed from the inner vessel, strong nitric acid and potassium chlorate added, and the fluid boiled and evaporated to a thin syrup, all the organic matter being broken up. 10 per cent. nitric acid was added, and the fluid transferred to the same cell and the current passed as before. In 30 minutes a well-marked black staining of the anode was apparent; this was dissolved off in 10 per cent. nitric acid as before, and gave positive tests for lead. A blank control made with the acid and potassium chlorate gave a negative result.

The serum had therefore taken up a proportion of the "lead albuminate" in an undissociated form which was not acted upon by the electric current under conditions closely resembling those of the animal's limb immersed in a saline bath. There is no support to the contention, therefore, that even if lead be stored up in the peripheral structures it is removable by electrical means. But the major part of lead recoverable from the body of persons dead of lead poisoning is found in the internal organs; thus Wynter Blyth[2] found 0·6 grm. in the liver, 0·003 grm. in the kidney, and 0·072 grm. in the brain. Hougounencq[3] found 0·258 grm. in the intestines, 0·005 grm. in the liver, and 0·0088 grm. in the brain of a person dead of lead poisoning. Dixon Mann[4] found the fæces contained large quantities of lead when administered by the mouth, and points out that the excretion of lead is mainly through the intestines; my own experiments[5] are in complete accord with this, and in many instances I have obtained considerable quantities of lead from the fæces of animals inoculated subcutaneously with soluble lead compounds, and I have also recovered amounts of lead from 0·001 to 0·008 grm. in the fæces of lead workers who were exposed to lead absorption, but who showed no clinical symptoms of lead poisoning.

In the paper quoted above it is stated that the lead present in the body at any time only amounts to a few grains, and that therefore the quantity eliminable by the electrolytic method is probably too small to determine, but in my experiments sufficient lead was present to be estimated by electrolysis when free from organic combination (0·0049 grm.); if, therefore, any deplumbising effect is produced by electrolytic baths the five experiments quoted would certainly have given some indication of its presence, but in every case a negative result was obtained. Ionic medication with iodine or salicylate is not comparable with the hypothetical removal of lead by ionic means, as in the application of drugs the electrolytes chosen are always dissociated, and their efficiency and penetrability depend upon their dissociation, while there is every reason to suppose that lead as an organic adsorption compound is not dissociated, as shown by the liver emulsion experiment. Lead chloride or any soluble salt of lead in the presence of albumin forms a thick, curdy, white precipitate, as does solution of albumose or peptone; any lead, therefore, circulating in the blood is unlikely to remain as a simple organic salt, but unless it does so—and there is no evidence to show that it does, and much to show that it does not—it will not undergo ionisation by small electric currents. Iron is easily deposited by electrolysis; if, therefore, Sir Thomas Oliver's contention is correct that lead is eliminated electrolytically by a double bath or any other method, the iron from the hæmoglobin of the red blood corpuscles should also be removed. Small quantities of lead no doubt have been found in the vessels in which lead workers' arms and legs were treated, as it is notoriously difficult to remove the last traces of lead from the hands of persons engaged in manipulating lead compounds, the fine dust penetrating the external layers of the epidermis and even filtering through the clothes. The hands and arms of a lead worker, after careful scrubbing with soap and hot water, may easily be shown to contain traces of lead.

The experiments *in vivo* and *in vitro* give no support to the contention that lead is eliminated from the animal body by the electrolytical methods tested, neither do they suggest any grounds for the adoption of electrolytic baths for the prevention or treatment of lead absorption or lead poisoning.

KING EDWARD'S HOSPITAL FUND FOR LONDON: STATISTICAL REPORT ON HOSPITAL EXPENDITURE.—The very useful annual report of the King Edward's Hospital Fund, which gives statistics relating to the ordinary expenditure of 106 London hospitals, has just been issued for the year 1913. Taken together these hospitals provide a total of 9171 beds, and the expenditure during the year under notice was £1,058,898. This sum includes maintenance, administration, rent, rates, and taxes, and interest on borrowed money, but excludes capital expenditure. Regret is expressed for the increase in the cost per bed occupied and per attendance of out-patients, first noted in 1911, which has continued, the addition in 1913 representing about £27,000. It is, however, pointed out that this increase is not necessarily attributable to a disregard of economy. As a means of assisting hospitals to discover and check where it exists any tendency to wasteful expenditure these reports serve a valuable purpose, and those responsible are to be congratulated on having produced such a careful compilation of facts relating to the expenditure of our London hospitals.

ELECTROLYTIC TREATMENT OF LEAD POISONING.

BY W. H. F. OXLEY, M.R.C.S. ENG., L.R.C.P. LOND.

IN further elucidation of the question as to the possibility of the removal of lead from the body in lead workers by means of electrolysis, as described by Sir Thomas Oliver,[1] I have performed the following series of tests on workmen showing signs of lead absorption and on lead-poisoned rabbits.

Experiment No. 1.—The first step was to apply the treatment to a number of workers in lead smelting, litharge making, and white lead making. Eight men—some with marked blue lines, some with faint blue lines, and others who showed the very earliest trace of blue line—were picked out. A proportion were old hands who showed, besides the blue line, some evidence of lead absorption, such as pallor, anæmia, and tremors, while others were perfectly healthy. All stages in the process of absorption were thus included. The electrical apparatus was set up as described by Sir Thomas Oliver, a voltage of 16 being employed, the positive electrode being placed in the foot bath and the negative in the hand bath, and a current of 25 ma. was passed through for 40 minutes (a dosage of 60 coulombs of electricity), and this was increased in the later baths to 35 ma. (84 coulombs). A bath was given on alternate days. Three of the men had 18 baths, 2 had 14, and the remainder 6, 7, and 8 respectively. The result in all cases was absolutely negative. There was no apparent change in the blue line except in the case of one man, who had been scrubbing his gums with a hard brush and had excoriated the mucous membrane. The signs of lead absorption were unaltered. All the men complained of feeling languid after the baths, and one stated that he had lost weight, while two had a little dermatitis on the legs and forearms.

Experiment No. 2.—It was next attempted to confirm Sir Thomas Oliver's statement that lead was found in the bath water and electrodes after use, and the following was the method employed. The electrodes were scrupulously cleaned with HNO_3, and the water used was ascertained to be free from lead. A man with a marked blue line was taken, and his arms and legs were well scrubbed. He was then placed in the baths for 40 minutes without current, when the water was again ascertained to be free from lead. This was done to avoid the possible error due to lead from the skin contaminating the water. The current was then turned on, and he was given 35 ma. for 40 minutes (84 coulombs), when the electrodes were removed from the water, thus stopping the current, and the water from both arm and foot bath was tested separately. No lead was found. Each electrode was then tested as follows: washed in HNO_3, solution neutralised with KHO, faintly acidulated with HCl, H_2S passed through. No lead present. On addition of Am_2S to solution a heavy black colour appeared, separating as a black precipitate. The precipitate was dissolved in HNO_3 and neutralised with KHO; on addition of KCNS a deep blood-red colouration appeared, indicating the presence of iron. A small piece of one of the electrodes was then tested; iron was present. It was thought possible that this iron precipitate might have been confounded with lead if no confirmatory tests had been made.

Experiment No. 3.—Another experiment was made on exactly the same lines as No. 2, except that the aluminium electrodes supplied with the apparatus were exchanged for 6 inch by 6 inch platinum sheets. No trace of lead was found.

Experiment No. 4.—A bath was given to 6 men successively, using the same water in each case. They were all old hands; 1 had had a previous attack of colic, 3 were definitely anæmic, and all had blue lines. Each was given a dose of 84 coulombs. No trace of lead was found either on the electrodes or in the water.

Thinking that it might possibly be contended that, although no lead was found in the baths, the passage of the electric current through the body might have the effect of rendering the lead more easy of elimination by the kidney the following experiment was performed.

Experiment No. 5.—A 24-hours' specimen of the urine of two old hands was examined for lead; none was present. On the following day a bath of 35 ma. (for 40 minutes) was given to each, and the 24-hours' urine again collected. No lead was found (the electrolytic method was used). A negative result was also obtained in testing the water and electrodes in this case.

The results up to this having been uniformly negative, it was decided to conduct a series of tests on rabbits and to submit them to a larger dosage of electricity. Two rabbits were taken.

Rabbit No. 1 was given 9 doses of 0·05 grm. of lead nitrate hypodermically and 3 doses of 0·025 grm. It lost weight rapidly, and on the twenty-second day developed paralysis, dying on the twenty-fourth day. The organs were examined, and 6·25 mgm. of lead recovered.

Rabbit No. 2 was given five doses of 0·05 grm. lead nitrate and three doses of 0·025 grm. It lost weight rapidly, and on the twenty-third day was given a bath of 30 ma. for 60 minutes, the fur on the legs having been removed. The water and the electrodes were then tested for lead, and none was present, but iron was again found in the washings from both electrodes, and a trace of copper in the water, which latter had probably come from the copper worm of the distillation apparatus. On the twenty-sixth day it was given a bath of two hours' duration at 35–40 ma., over four times the dosage employed by Sir Thomas Oliver. No lead was present either in water or electrodes. From the thirty-second day it was fed with 0·05 grm. daily for four days and 0·1 grm. for six days. It lost over 100 grm. in weight and became extremely weak. It was then given a bath of 36 ma. for four hours. No lead was found in the bath or electrodes. It was then killed, skinned, and the body bathed with a current of 90 ma. for three hours. No lead was found. 30 grm. of the liver were made into emulsion with physiological saline solution and placed in a dialyser floating in distilled water, and a current of 35 ma. passed through for 40 minutes. The water and electrodes were then examined for lead with a negative result. A subsequent chemical analysis of the liver showed it to contain 2·2 mgm. lead.

Conclusion.—These results would appear to show that the treatment as described by Sir Thomas Oliver has no effect upon the blue line, and does not extract lead from the body. The usual tonic effect of an electric bath was not noted, and I am forced to the conclusion that no practical good would result from the regular treatment of lead workers in this way. The experiments with the rabbit show a consistently negative result even under more favourable conditions for lead extraction than can be obtained in the human subject.

A consideration of the conditions under which we are working will, I think, show that these negative results are only what one would expect. The body may be regarded as a mixture of different salts in solution as electrolytes, of a strength of about 8 per 1000, added to which there would be a small percentage of some lead compound or compounds, the exact nature of which we do not know, nor do we know whether they are present in the condition of dissociation necessary for them to become electrolysable. However that may be, the amount is very small; taking Legge and Goadby's figure of 0·005 grm. per kg. as the minimal poisoning dose,[2] the proportion of lead ions to tissue ions would be not more than 1 to 1600. Now it has been found that in a solution of mixed electrolytes all the electrolytes assist in the conduction of the current, and take part in the migration towards the poles, the ratio of concentration of ions not undergoing change.[3] They are not all deposited on the electrodes, but they are using up the current, thus leaving very little to take part in the electrolysis of the lead. Further, if the proportion of any one electrolyte be very small, it is impossible to extract it without a large increase in the potential.[4] Exact figures are impossible to give, but taking the tissue ions as being very largely sodium, a calculation will show that the amount of electricity available for the electrolysis of the lead would not be sufficient to deposit more than 0·04 mgm. of lead per bath, which is quite a negligible amount.

---

[1] THE LANCET, August 23rd, 1913, p. 527.

[2] Lead Poisoning and Lead Absorption.

[3] Leblanc: Electro-chemistry.

A further difficulty in the extraction of lead from the body by this means appears to have been overlooked. I refer to the extremely slow rate of the penetration of ions through an animal membrane or similar substance. Lodge,[5] using a tube of gelatin, found the velocity for hydrogen ions to be 10·8 mm. per hour, and for sodium ions 1·26 mm. Sloan[6] found the penetration of Cu ions through the ox stomach with a current of 5 ma. for five hours to be 3 mm., and in white of egg, with an amount of 100 coulombs, after two hours the penetration was 2·5 mm.

Taking these two factors into consideration—first, the large proportion of total current used up by the tissue ions, and secondly, the slow rate of penetration of the ions through the skin—it would appear that the total possible effect of a bath would be to remove from the superficial layers of the skin an amount of lead not exceeding 1/7500th part of a grain. The conditions are the reverse to those obtaining in ionic medication, where concentrated solutions are used, and the whole of the current is, near the surface at any rate, available for the driving inwards of the drugs used. It is, of course, possible that the effect of the baths may be to increase the elimination of lead by the ordinary channels. Oliver, however, states that after the baths the excretion of lead by the kidneys is diminished, and in the two examinations made by me no lead was found after the baths.

I am much indebted to Dr. A. W. Stewart, of the Royal Institute of Public Health, and to Mr. Cowan, manager of Messrs. Lock and Lancaster, Bridge-road, Poplar, for the help given to me in these investigations.[7]

East India-road, E.

OBSERVATIONS ON THE IMPROVISATION OF APPARATUS IN THE TREATMENT OF CERTAIN FRACTURES IN MODERN WARFARE.

BY J. H. WATSON, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGEON, VICTORIA HOSPITAL, BURNLEY;
AND
T. SNOWBALL, M.B.

II.[1]—TREATMENT OF FRACTURES OF THE UPPER ARM.

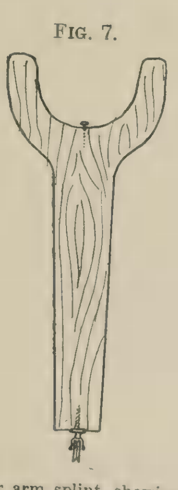
THE great necessity for improvising suitable apparatus for fractures in modern warfare is most emphatically pointed out by von Saar in his experiences of the Balkan war. Considering that the large number of wounded suffering from fractures averages almost 50 per cent., he was amazed at the chaos which prevailed as to their treatment. Even in well-equipped base hospitals they were submitted to all sorts of rough-and-ready methods. No particular routine was adopted; each surgeon employed his own peculiar methods, often devoting his more particular attention to operative cases whilst frequently grossly neglecting the fractures. We cannot do better than quote von Saar's own words here:—

> I believe that the first interest of the war surgeon should be directed to the wounded soldier with the view not only to his recovery, but also to fit him for an early return to active service, without any regard to purely medical or surgical interest; in this connexion a soldier with a well-healed fracture of the extremities is of just as much value as one who has had a successful trephining or laparotomy. I am convinced that with a good form of fracture treatment in war, we can be of the greatest service to the individual and consequently to the State.

From a large experience of fractured upper extremities the best results were obtained by means of Borchgrevink splints which were modified to some extent. It must be remembered that fractures in war from bullet wounds are for the most part complicated—complications from infection arising from clumsy first aid or the want of first aid at all. They are almost invariably comminuted, and usually of such an extent that there are considerable deformity and shortening. Such cases cannot be kept in position with simple splinting (even the triangular splints of Middeldorpf and von Hacker soon become displaced), and require an extension apparatus if anything like a good result is to be obtained. There are many ways of applying extension to the arm and forearm, mostly cumbersome, by means of a weight and pulley, but scarcely adaptable even at a base hospital. Moreover, one is so confused by the various conflicting opinions of numerous writers that it is difficult to formulate definite lines. We repeat again that the method for adoption in modern warfare is that which is most easily carried out and which is of proved efficiency, and for this reason we give in detail von Saar's modification of Borchgrevink's method of elastic traction.

The splint is made of soft wood about ½ to ¾ inch thick. The upper end is in the shape of a horseshoe, the width of the concavity being such as easily to fit the shoulder when well padded; the shaft is about the width of the arm, and is long enough to extend some 3 or 4 inches below the elbow. (Fig. 7.) The extension with this splint was obtained in the following way: A piece of adhesive plaster 2 inches wide is applied to the inner and outer aspects of the arm, leaving a loop

FIG. 7.



Upper arm splint showing pulley and nail inserted.

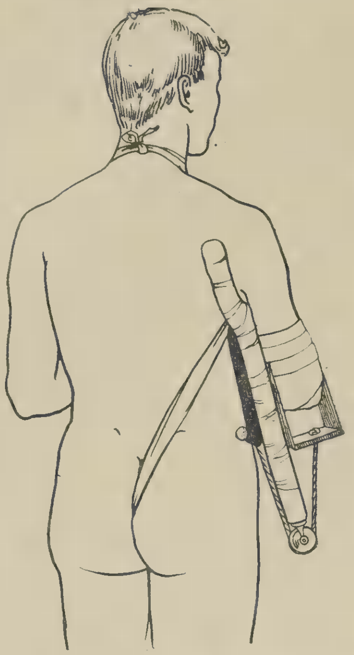
for the insertion of a rectangular piece of wood perforated at the centre and slightly wider than the arm at the epicondyles, which are protected from pressure by a gauze bandage. This plaster is maintained in position by imbricating narrow pieces of leucoplast. (Fig. 9.)

FIG. 9.

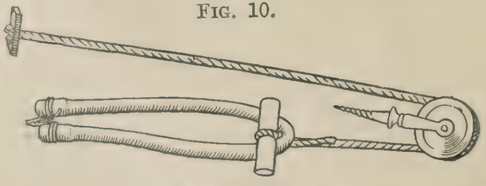


View of the lie of the splint from behind without arm bandage.

Now drive a strong nail into the concavity of the fork of the splint, leaving about ¼ inch free. The purpose of this nail is to suspend the elastic traction apparatus. The forks of the splint are then padded with wool, which may be secured by a few turns of bandage. The side which is to lie nearest the inner side of the arm is also suitably padded and a screw pulley is fixed in the lower end. (Fig. 9.) An assistant places the splint in position, the padded limbs of the fork resting lightly on the anterior and posterior folds of the axilla. A perineal band is affixed, which we have found to be most easily done by taking a loop of bandage, fixing it to the base of the posterior horn of the splint by a clove hitch knot, taking the double loop of the bandage under the perineum, and twisting one end round the base of the anterior horn and tying it firmly to the other end. (Fig. 8.) This prevents both displacement upwards and pressure on the axilla. (Fig. 9.)

We will now describe in detail the elastic traction apparatus, particularly as it occurs again in the description of the forearm extension. (Fig. 10.)

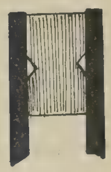
FIG. 10.



Elastic traction apparatus.

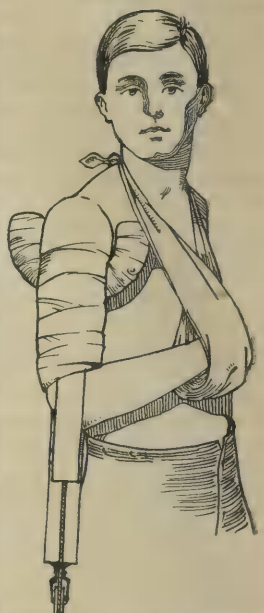
A piece of drainage-tube about the thickness of a finger and about 14 inches long is taken, the open ends of which are plugged with a piece of round wood about ⅔ inch long in which a deep notch is cut in the centre in order that one end of a strong piece of string may be tied over the groove on the outside of the tube and so prevent slipping. (Fig. 11.) The other end of the string is similarly tied to the other end of the rubber tube, leaving a short intervening loop about 1 inch to 2 inches long; by this means the drainage-tube is hung in loop fashion on the side of the splint nearest the body. (Figs. 8 and 9.) The little piece of wood which anchors the cord in the loop of drainage-tube is improvised out of a short piece of soft wood made round or square as desired, and notched in the centre to receive the string. If the extension begins to slacken it is easily tightened by shortening the string. The forearm is supported at right angles to the arm by a simple wrist sling, and the arm is bandaged securely over the splint. (Fig. 12.)

FIG. 11.



End of rubber tubing showing manner of inserting plug.

FIG. 12.



Anterior view of splint fixed in position. (In this diagram the splint has been drawn too long.)

The advantages, in brief, are: 1. It is comfortable and not easily displaced, comparing favourably with the usual triangular splints. 2. It permits any degree of extension likely to be required, and the amount is easily regulated. 3. During the day the patient can go about with it. At night the arm is supported by a pillow. 4. It has been tried with many severe fractures of the upper arm and has been found to be efficient.

(To be continued.)

A CENTENARIAN.—Mrs. Margaret French died at Hampstead on Sept. 26th in her 101st year.

BRISTOL GENERAL HOSPITAL.—At the half-yearly meeting of this institution what would have been an interesting report in time of peace gained additional interest from its references to the war. It appears that when war broke out an urgent request from the Royal Infirmary for beds into which some of their patients might be transferred was received, the infirmary committee having promised some time ago to hand over the whole of their institution to the War Office if it was wanted. When the infirmary authorities decided that it would be impossible to carry out this project fully they notified the General Hospital that there would be no need for the transfer of beds that had been arranged for. The hospital at once decided to open the new maternity ward, giving preference to the wives of soldiers and sailors at the front, at the same time holding themselves in readiness to offer beds to the War Office, should the need arise. As for the ordinary work of the institution, it showed an increase in in-patients, out-patients, and the daily average of occupied beds over the preceding year; both income and expenditure also showed an advance, the former, however, by twice as much as the latter. Four members of the honorary staff and two of the residents are with the army or navy, while nearly half the *à la suite* staff of the Second Southern General Hospital is composed of members of the honorary staff of the Bristol General Hospital. The hospital pathologist and several nurses are also serving with the Territorial Army.

Reviews and Notices of Books.

Dietetics, or Food in Health and Disease.

By WILLIAM TIBBLES, L.R.C.P. Edin., M.R.C.S. Eng., M.O.H., LL.D., M.D. (Hon. Causâ) Chicago. London: Baillière, Tindall, and Cox. 1914. Pp. 627. Price 12*s.* 6*d.* net.

THIS is an admirable work, full and yet concise, well arranged, carefully planned with a due proportion of space to each division of subject, and written so simply and clearly that it is quite readable in spite of the enormous mass of detail with which it is loaded. If there are sections which seem unduly long, such as the chapter on vitamines, their length is necessary for the careful estimation of a large bulk of new, original, and important experiment.

The book is divided into two main sections, of which the first treats of the physiology and physics of food. The first chapter, which deals with the chemical composition and classification of foods ends with 11 pages of tabular statement concerning every conceivable item of European diets, with their percentage compositions and their heat and food values. But the author is far too conversant with his subject to take the mere calorie value of an article as a bald index of its value as food, and wisely considers in one admirable chapter the heat value and digestibility together; for we live not by the food which we eat but by the food which we digest, a point which is illustrated later on by Dr. Tibbles's criticisms on "Fletcherism." The calorie value of food is not changed by mastication, but its digestibility is increased considerably.

By far the most important chapter in the first, or theoretical, part of the book discusses the amount of food required. It consists of 75 pages, of which much is devoted to the vexed question of protein requirements. The author's conclusions are very carefully drawn. The consumption of a greater proportion of protein than the essential minimum (compare Chittenden's standard) is advantageous by acting as a stimulant to metabolism and a ready source of energy. A very temperate and judicial survey of the use of stimulants closes the first part of the volume, and a far larger part is devoted to diet in various diseases.

Though little of this latter part of the book is original we can testify to the merits of the compilation. The striking feature is the care with which space is allotted to those conditions in which diet is of most importance, such as the indigestions, the diarrhœas, gout, and, of course, diabetes. A very full consideration is given to the vitamines and the group of tissue degradations now known as the deficiency diseases, among which beri-beri, scurvy, and pellagra, may be ranged. Dr. Tibbles's account is full, exact, and clear, while it is brought well up to date, and includes a résumé of the recent work of Osborne, Mendel, and others on the "insufficient" proteins. In following the phosphorus deficiency theory of Schaumann it is interesting to note the high phosphorus-value of rye-bread, despised of English politicians.

This book is a storehouse of information which will yield a fruitful supply for many years.

Anemia and Resuscitation: an Experimental and Clinical Research.

By GEORGE W. CRILE, Professor of Surgery, Western Reserve University Medical College, Cleveland, Ohio. London and New York: D. Appleton and Co. 1914. Pp. 305. Price 21*s.* net.

THE author makes "an endeavour to solve practical clinical problems which both the surgeon and the internist confront." The protocols of the author's experiments are published in considerable detail, with a view to save other workers unnecessary repetition.

Anæmia of the central nervous system—experimental and clinical—and cerebral anæmia through ligation of the common carotid arteries are first considered (pp. 4–72). In order to determine the limits of recovery after a total anæmia of the central nervous system 30 dogs were anæsthetised by chloroform and resuscitated after a lapse of from 3–14 minutes. If resuscitated in less than 5 minutes the recovery of function was rapid, and was strikingly free from the after-effects that characterised longer periods. Of 12 animals subjected to anæmia from 7–8½ minutes, only one recovered after 7½ minutes of anæmia. The remaining dogs all died. The neurocytes of the fatal cases—examined by the Nissl method—showed not only chromatolytic changes but also those indicative of cell death. Marchi's method revealed degeneration of nerve fibres. The important conclusion is reached that in anæsthetised dogs the average limit of total cerebral anæmia, estimated from cessation of the heart sound to return of circulation, which admits of recovery, is between 6 and 7 minutes. An interesting analysis from the literature of 500 cases of ligation of the common carotid artery is given. The author advocates, as a preliminary step to permanent ligation of the common carotid artery, that temporary closure by means of a clamp should be done when possible. We think that he is more than justified in his contention as well as in his emphatic and convincing pleading for the course he so strongly recommends. Closure of the common carotid, however, does not arrest hæmorrhage so completely as does closure of the external carotid.

Anæmia of voluntary muscles in man and animals, occlusion of the abdominal aorta, and ligation of the main arterial trunks of the leg in man are next dealt with; then follows a chapter on ischæmic paralysis and the clinical applications of the foregoing phenomena. Roughly, it may be taken that anæmia of a dog's thigh of seven hours' duration, brought about by an Esmarch bandage which was tightened until arterial pulsation ceased, the dog being under morphia and light ether anæsthesia throughout the time of application, is followed by permanent paralysis. The knee-jerk is lost after six hours' anæmia. Indeed, arrest of the circulation of an extremity for more than two hours is not wholly safe, while the longer the anæmia beyond two hours the greater the degree of temporary or permanent paralysis. In the absence of personal clinical experience 50 cases of obstruction of the abdominal aorta are collated, examined, and criticised. Perhaps the practical surgeon will read and assimilate the author's cogent remarks on the errors in the treatment of fractures, the use of the frequent external application of alcohol in preventing the formation of bed sores, flap tension, and suture tension. Now that abdominal operations are so frequently performed no chapter in the whole of this most suggestive contribution to physiology and surgery is more illuminating than that on anæmia of the small intestine and the effects of interference with the circulation for different lengths of time under different conditions. The important principle is established in operations for gangrene of the intestine that the patient must be protected at all hazards against the absorption of the exceedingly toxic fluid in the gangrenous tissue. The toxin of anæmic gangrene requires several hours to cause the first symptoms. The author considers that in cases of acute intestinal obstruction the most important lesions are in the brain. Anæmia of the kidneys and spleen is considered. For the surgeon what the author has to say about resuscitation of the body as a whole, including resuscitation of the respiratory and circulatory apparatus and also about his own method of resuscitation, will prove well worthy of study.

This is a contribution to practical surgery, based primarily on clinical observation and experience, which the author and his associates have illumined by experimental physiological research of far-reaching importance. The author proves conclusively the immense advantage of studying all surgical problems from a physiological as well as from a clinical point of view. It is worthy of the highest commendation.

A Text-book of General Bacteriology.

By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology in the University of Chicago and in Rush Medical College. Fully illustrated. Fourth edition, thoroughly revised. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 650. Price 13*s.* net.

ORIGINALLY published in 1908, this book has now reached its fourth edition and evidently meets the needs of a considerable number of readers. The previous editions have been reviewed at length in THE LANCET. The arrangement and scope of the work are similar to those of most other bacteriological text-books, and it has the merits of lucidity and systematic planning in common with other works of American authorship. It claims to differ somewhat from other text-books on bacteriology, however, in that it treats the subject as a part of a general scientific education rather than from the narrower standpoint of the technical instruction of the medical student. The new edition has been somewhat enlarged, and certain sections have been rewritten and others rearranged. The most important change is the introduction of a chapter on the filterable viruses which though in no sense complete yet gives a succinct account of those of the greatest pathological importance. The section on leprosy has been added to and now represents modern views more closely than did the previous edition. Whooping-cough is treated more fully, and other alterations have been made to bring the work up to date. The illustrations are good and well selected from classical works, and the book is excellently produced as were the previous editions.

JOURNALS AND MAGAZINES.

Indian Journal of Medical Research. Vol. I., No. 4. —This number contains a reprint of the very important sanitary "resolution" of the Government of India, dated May 23rd, 1914, in which is given a summary of the history of the attempts made since 1859 to improve the health of the native populations and to develop sanitary organisation throughout the country. It also summarises the advances which have been made of late years in our knowledge of certain diseases and their prevention, such as malaria and plague. The resolution may be regarded as setting out to all concerned the present sanitary policy of the Government of India. In THE LANCET of July 18th we gave a résumé of this important document, which shows how much progress has been made during recent times in the sanitary administration of India. The next three original articles relate to the subject of kala-azar. The first of these is by Dr. R. Row, of the F. D. Petit Laboratory, Byculla, Bombay, describing, with illustrations, experimental leishmaniasis in the monkey and the mouse induced by the parasites in culture. The second article is by Dr. Vishnu T. Korke, who is engaged on special duty in connexion with the kala-azar inquiry, and is entitled "A Note on the Production of Localised Lesions by Leishmania Donovani in Macacus Sinicus." The third deals with the Epidemiology of the Disease, and is contributed by Captain F. Percival Mackie, I.M.S., in the form of a report on Kala-azar in Nowgong (Assam), illustrated by maps and charts, and giving also an account of a series of experimental observations made on animals. Some attention was devoted by Captain Mackie to the question of human infection through the agency of bed-bugs, but so far no confirmation of this agency has been obtained. Captain Hugh W. Acton, I.M.S., and Captain R. Knowles, I.M.S., furnish a joint paper, with illustrations, respecting their Studies on the Halteridium Parasite of the Pigeon, Hæmoproteus Columbæ (Celli and San Felice). A Practical Note on the Treatment of Swamps, Stream-beds, Ponds, Wells, and Pools, with a view to the Destruction of Mosquito Larvæ, is supplied by Mr. H. C. Wilson, piscicultural expert to the Government of Madras. Captain E. C. Hodgson, I.M.S., contributes a preliminary note, with map, on Malaria in the City of Madras. The Misleading Reactions obtained with Precipitating Antisera, and How to Avoid Them, forms the subject of a joint paper by Lieutenant-Colonel W. D. Sutherland, I.M.S., and Assistant Surgeon G. C. Mitra, I.M.S. A preliminary note on experimental researches connected with the standardisation of vaccines is contributed by Captain H. C. Brown, I.M.S., of the Central Research Institute, Kasauli; and Military Assistant Surgeon G. H. Blaker, of the same institute, supplies a note on the preparation and standardisation of typhoid vaccine. The Agglutination Reaction after Typhoid Inoculation is the title of a short paper with accompanying charts furnished by Assistant Surgeon A. W. Dyer, of the Station Hospital, Kasauli. A simple method of estimating the amount of gas produced by gas-forming bacteria is described by Captain J. Cunningham, I.M.S. The last article is a joint contribution by Captain J. A. Cruickshank, I.M.S., and Captain R. E. Wright, I.M.S., both of the Pasteur Institute of Southern India, Coonoor, on Filariasis in Cochin, with numerous illustrations. It appears from this paper that nearly 21 per cent. of the people of Cochin harbour microfilariæ in their blood, and that close upon 13 per cent. suffer from elephantiasis. About 33 per cent. of the general population show definite signs of filariasis in one way or another. The filaria in Cochin is almost certainly filaria bancrofti, and the culex fatigans is regarded there as an efficient mosquito intermediary, though others may also act as carriers of the infection.

Annali dell' Istituto Maragliano. Vol. VII. Fasc. 5. June, 1914. Piazza del Popolo 11, Genoa.—The Maragliano Institute, founded by the professor of clinical medicine at the University of Genoa for the study of tuberculosis and other infective diseases, publishes in this number four interesting articles. Dr. A. Connio gives the result of his experiments on the influence of the method of sterilisation on the toxicity of dead tubercle bacilli. He found that the toxicity was definitely influenced by the method used. It was little changed by a temperature of 70° C., but considerably by one of 100°; little affected by chloroform, but markedly diminished by extraction with ether. Investigations on the herpes of pneumonia by Dr. C. Trevisanello disclosed the fact that the pathogenic germ is met with in these eruptions in a pure state. Such diplococcus is in a condition of attenuated virulence, but may acquire its primitive virulence when subject to several passages in culture media, and may assume all the special characteristics of Fraenkel's pneumococcus. This paper has a practical application from a prophylactic point of view. Dr. A. Bertolini contributes a lengthy paper on the Influence of Hepatic Autolysis on the Toxicity of Diphtheria Toxin, a paper of considerable interest, although not pretending to apply to human pathology the results of laboratory experiments. The final article, by Dr. Barlocco, treats of the chemio-physical relations between the cerebro-spinal fluid and the blood serum in healthy and diseased subjects.

Journal of Laryngology, Rhinology, and Otology.—The issues for June and July contain a translation of a paper entitled "The Rhinogenic and Otogenic Lesions of the Third, Fourth, Fifth, and Sixth Cranial Nerves," by Ladislaus Onodi, of Budapest, which was read and preparations shown at the annual meeting of the Belgian Society of Otology, Rhinology, and Laryngology at Brussels in July of last year, when preparations were shown. The author describes the anatomical relationships of the sphenoidal sinus to the nerve-trunks of the cranial nerves liable to become involved. He then discusses the etiology of rhinogenic and otogenic lesions of the oculo-orbital nerves, first consideration being given to the infection and the extension of the pathological process. The number of such cases which have been published is somewhat small, and this enhances the value of the paper which is well illustrated with photographs of the author's anatomical preparations. A good bibliography is appended. The August issue contains an article by J. van der Hoeve Leonhard, of Amsterdam, entitled Bi-submucous Resection of the Septum Nasi. The author's modification of the typical operation is described and is intended for appropriate cases to avoid perforations of the septum in cases in which the latter could scarcely be prevented in proceeding according to the usual methods.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

SANAPHOS.

(THE BRITISH MILK PRODUCTS COMPANY, LIMITED, 69–70, MARK-LANE, LONDON, E.C.)

Sanaphos is described as a phosphated milk product. According to our examination it is sharply distinguished from casein preparations which are said to be reinforced with organic phosphorus compounds, inasmuch as no less than 80 per cent. of sanaphos is rapidly soluble in cold water, and amongst the soluble portions we find that 25 per cent. consist of casein itself containing also milk albumin. Associated with this soluble casein is an organic phosphorus compound showing a total of phosphorus content of 0·70 per cent. With water the powder gives a fluid which tastes and appears like milk. It seems evident from this that the milk basis produces milk again on restoring to it the water which has been eliminated in the desiccating process. It is, however, practically free from fat, which in a dry powder is apt to get rancid owing to oxidation. Further, the uniform fluid so obtained contains the activities of raw new milk according to the well-known tests for oxidases. The presence of the active enzymes of raw milk is, of course, of the utmost physiological importance. In pure casein preparations these ferments are not likely to be present owing to the chemical and physical methods employed for its separation. In sanaphos, therefore, in addition to the presence of admittedly easily assimilable organic phosphorus compounds, the vehicle is "live" milk in which in powdered form are preserved the physiologically active enzymes. The claims in regard to this preparation as to its value in neurasthenia, enfeebled nervous conditions, mental and physical fatigue, and so on, should receive attention, since assistance is reckoned to be given to the assimilation of organic phosphorus compounds by the activities of ferments.

ACROSYL.

(THE ACROSYL COMPANY, SUTHERLAND HOUSE, LLOYD'S AVENUE, LONDON, E.C.)

Acrosyl is a clear, bright fluid containing cresols of special germicidal activity in an alkaline medium and soap. It mixes with water in all proportions, giving a perfectly clear fluid. On analysis by a method which originated in THE LANCET Laboratory[1] the cresols present amounted to approximately 50 per cent. This method is based on the separation of fatty acids from the phenols or cresols by the use of baryta. The claim made in regard to germicidal activity is that acrosyl is rather more than double that of an equivalent of carbolic acid (2·07). In separating the cresols we found that they showed an iodine value equal to half that of pure phenol. This substantiates the stated carbolic co-efficient of 2·07. Apparently the iodine value is inversely that of the germicidal value expressed as a carbolic acid co-efficient. Soapy and alkaline solutions of powerfully germicidal cresols prepared on the lines of acrosyl are widely appreciated in surgical work on account not only of their antiseptic value but because also of their important detergent and cleansing properties.

HÆMORRHOIDAL SUPPOSITORIES.

(MESSRS. ALLEN AND HANBURYS, LIMITED, PLOUGH-COURT, 37, LOMBARD-STREET, LONDON, E.C.)

These suppositories suggest a modern method in regard to the treatment of hæmorrhoids and inflammatory conditions of the rectal mucosa. The active constituents are respectively iodol, resorcin, suprarenal extract, and balsam of Peru. The advantages of this combination for the particular purpose will be easily recognised when the antiseptic, antihæmorrhagic, and soothing activities of the successive ingredients are considered. The suppositories are shaped conveniently for application, and the fatty basis readily distributes its medicaments at the body or rectal temperature.

HAIR TINT (BROWN).

(MESSRS. HINDES, LIMITED, 3, GREAT QUEEN-STREET, KINGSWAY, LONDON, W.C.)

We have examined a sample of this preparation with the view of determining whether it contained any constituents which could be regarded as of an injurious nature. We are able to say that it contains no scheduled poison, and on the constituents being disclosed by analysis it is obvious to us that it can be used for the purpose claimed with safety so long as the instructions for its use are followed.

CHELONA WINE (TURTLE PORT).

(THE MEDICAL ENTERPRISE SOCIETY, LIMITED, 25, PALACE CHAMBERS, 9, BRIDGE-STREET, WESTMINSTER, S.W.)

We have had the opportunity of examining the turtle basis which is employed in producing this wine. It consists of a watery extract which is subsequently evaporated to dryness. It contains just over half its weight of real proteins. It resembles meat extract in appearance, showing the presence of 33·03 per cent. of water, and has that peculiar flavour which those familiar with the attractions of turtle soup will easily recognise. The same flavour will be recognised in the wine, and analysis shows that in the process of combining with it turtle extract the proteins amount to 0·286 per cent., representing approximately 1·4 per cent. of raw turtle. Further results of analysis give the following figures: Total solids, 7·46 per cent.; mineral matter, 0·30 per cent.; alcohol by volume 21·19 per cent., and sugar 7·10 per cent. We do not doubt at all that the wine contains a moiety of the nourishing constituents of the turtle, but in the process there must be waste of valuable material, inasmuch as the nutrient portions of the turtle are not compatible with a wine of the alcoholic strength of that submitted to us, while the natural tannin of all genuine wines is opposed to a complete solution of proteins. In any case, when alcohol is a medium the prescription must clearly only be admissible under the direction and control of the medical adviser.

---

[1] Vide THE LANCET, Nov. 13th, 1909, p. 1456.

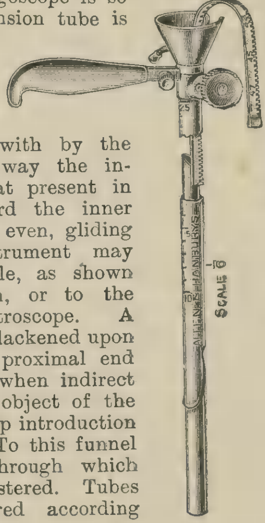
H.P. SAUCE.

(MIDLAND VINEGAR COMPANY, LIMITED, ASTON CROSS, BIRMINGHAM.)

We have examined a sample of this condiment which has been submitted to us, chiefly in regard to its freedom from impurities that may be incidental in pickle manufacture. It contained no metallic impurities or objectionable preservatives. Careful search was made in particular for copper, but none was found. The pickle, we are told, is made under strict hygienic precautions, and we can find no reason for discrediting this statement, and the evidence is in favour of pure and good materials being employed in its preparation. It makes an appetising adjunct to food.

New Inventions.

A NEW FORM OF BRONCHO-ŒSOPHAGOSCOPE.



THIS form of broncho-œsophagoscope is so designed that the inner or extension tube is extended by means of a screw adjustment, on the principle of the coarse adjustment of a microscope, and it is constructed in such a manner that its lumen is not interfered with by the mechanism adopted. In this way the inaccurate and clumsy method at present in use of forcibly pushing forward the inner tube is avoided, and a smooth, even, gliding motion substituted. The instrument may be fitted to an ordinary handle, as shown in the accompanying diagram, or to the handle of a Brüning's electroscope. A detachable and slotted funnel, blackened upon its inner aspect, fixed to the proximal end of the outer tube, is provided when indirect illumination is employed, the object of the slot being to permit of the deep introduction of instruments with handles. To this funnel is attached a small tube, through which an anæsthetic may be administered. Tubes of different sizes are required according to the age of the patient.

The makers are Messrs. Allen and Hanburys, Limited, of Wigmore-street, London, W.

Manchester. WILLIAM MILLIGAN, M.D., C.M. Aberd.

APPARATUS FOR ARTIFICIAL PNEUMOTHORAX.

THE many controls necessary in the usual forms of apparatus for artificial pneumothorax induction have been abolished by an addition I have designed. The gas tubes from the oxygen and nitrogen bottles, the gas delivery tube to the T piece on the manometer, the water tubes from gas bottles and reservoir are all brought to a single controlling regulator fitted with a pointer indicator. This has been made for me by Messrs. Reynolds and Branson, of Leeds, and is here illustrated. The whole flow of gas and water in every direction is controlled by one tap with a pointer on an indicator showing what is taking place. Whenever the pointer is pointing to the word "closed" the needle in the patient's chest is only in communication with the manometer, and *all other openings* are shut off. The pressure attained in the chest can thus be read whenever desired during the operation, all hydrostatic pressure being eliminated. In this way one tap controls the apparatus, closing the needle during re-charging the gas bottles, or at any moment, and controlling immediate change from one gas to the other during the filling of the chest.

FIG. 1.

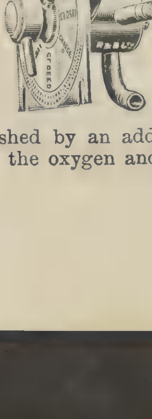


FIG. 2

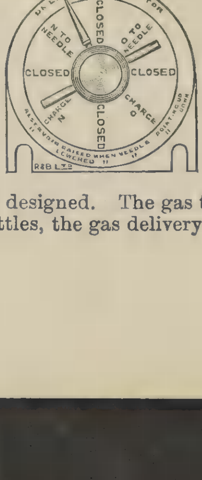

FIG. 3.

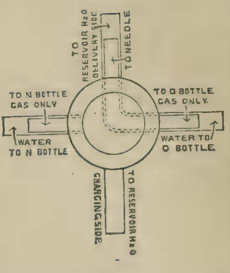

FIG. 4.

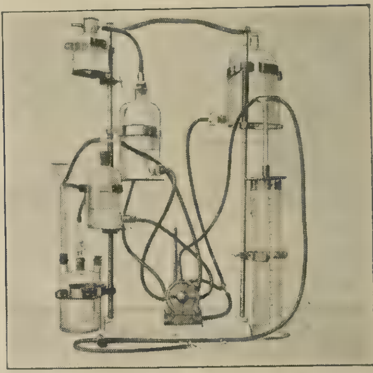

Regulator *in situ* applied to Dr. Lister's modification of Dr. de C. Woodcock's apparatus. This prepares its own oxygen as well as nitrogen. (Made by Messrs. Reynolds and Branson.)

This regulator it is hoped will prove an assistance in enabling the single-handed operator to devote his whole attention to watching the manometer which is in communication with the needle in the chest.

To diminish the risk of puncture of the lung to a minimum I have had made for me by the Holborn Surgical Instrument Company a semi-blunt needle of small calibre with a lateral aperture very close to its point. It is here illustrated. This needle is introduced through a little silver cannula guarded by a flat plate one-quarter of an inch from its end. This is introduced by means of a sharp trocar through the skin and superficial tissues in the intercostal space. The trocar is withdrawn, leaving the little cannula fixed in the superficial tissues. The hollow semi-blunt needle is then introduced through the cannula which it fits. Although it is impossible to guard absolutely against risk in the operation for producing artificial pneumothorax, yet simplification of *control* of the hydrostatic apparatus for the transfer of gas to the chest and the substitution of a semi-blunt needle introduced through a guarded cannula may help to prevent some accidents in the hands of those who do occasional operations, especially practitioners carrying out refills.

THE LANCET.

LONDON: SATURDAY, OCTOBER 3, 1914.

The Care of Our Wounded.

WE published last week a brief preliminary sketch of the way in which the care of the sick and wounded in war is organised and undertaken by the Royal Army Medical Corps. The scheme was laid down many years ago by Sir THOMAS LONGMORE and lends itself to various developments. As methods of transport and of intercommunication improve it can be adapted to all the modifications necessary, and the sick or wounded man can be maintained throughout the operations under the protection of medical care. From the firing line he is drawn into shelter; first aid having been rendered he is transported without delay to a clearing hospital where treatment suitable to his case can be more deliberately supplied; from the clearing hospital he is removed to a base hospital with all the promptitude which transport can provide. Nothing is wanting theoretically in the scheme, which is as sound to-day, when ambulance trains and motor lorries can be employed, as it was when the Crimean veteran drew it up. But in no department of war is it more difficult to ensure that practice shall follow theory than in the management of the sick and wounded, for circumstances may arise in the general conduct of affairs so disconcerting to all medico-military plans that temporary breakdown may become inevitable.

In a war like the one which is now raging, along enormous battle fronts, it is perfectly certain that, where each side is alternately advancing here and retreating there, the medical services of the Royal Army Medical Corps, supplemented by the St. John Ambulance Association and the British Red Cross, cannot always remain available for the sick and wounded in every stage between the front and the base. Plentiful information has reached us already how effectively the Royal Army Medical Corps have done their work, while the Casualty Lists sufficiently show with what devotion and with what personal risk this work has been done; but stories have also been published suggesting that in other places the wounded have failed to get adequate attention or transport. This is a matter upon which the public is rightly sensitive, so that we think it fair to point out how inevitable it is that any general scheme should find itself unable to cope in detail with all the circumstances that may arise over two hundred miles of desperate fighting. Let us look back at those terrible days which marked the arrival of our Expeditionary Force at the front. That Force was immediately compelled to make prompt retirements against overwhelming numbers, and was subjected on many occasions to heavy slaughter. It is obvious that the battle-fields upon which our wounded lay were immediately occupied by the enemy, that the places of retirement selected for dressing-stations could no longer be used, and that situations designed for clearing hospitals came early within the range of attack. In these circumstances the recognised routine for collecting the wounded and for sorting and "evacuating" them was thrown out of gear. The fact is so clear that it calls for no explanation, and the result so obvious that it need not be dwelt upon. All that a medico-military service could do in such circumstances was done. Every endeavour was made to collect as many wounded as possible, and, despite the personal risks incurred in the task, it was attempted to give first aid to those collected, and where possible to arrange for their transport to more permanent shelter. In such circumstances the accomplishment of any design depends practically upon the tide of the battle, upon the amount of transport available, and upon the attitude and demeanour of the enemy. In adverse circumstances no more than this can be done by the best organised service in the world, who may have to make the best of a terribly bad job. The medico-military service, at any rate in the advance part of its work, must share the fortunes of the army which it accompanies, and of which it is an integral part; and if the army has to give way to superior force, to retreat, and possibly to leave behind that which cannot keep pace with a retreat, the pre-arranged care of the wounded will become disorganised, and grievous agony and sad loss of life must follow.

We publish in another column interesting communications from Dr. JAMES DONELAN and Dr. KNOWSLEY SIBLEY which indicate that throughout the war the British and French armies have made every attempt to send cases from the field-dressing stations as rapidly as possible to the large base hospitals, which have been prepared in, among other places, Paris, Rouen, and Dieppe. Now base hospitals are arranged presumably in a place out of the sphere of the enemy's activities, and here the arrangements can be made with deliberation and can be thought out beforehand. Although they are of course dependent in a secondary manner on the course of the war, there should not be any reason to alter them from day to day or hour to hour. As long as the lines of communication are preserved the transport of the wounded by train, lorry, or, in some cases, water, should proceed systematically; the treatment at the hospitals should be scientific and thorough, the nursing and feeding arrangements should be ample, the arrangements for passing the convalescent patients out, so as to make room for new patients, should work well, the horrors of infection should be expected and dealt with. Failure in any of these respects at a base hospital must be explained, while a breakdown in the fighting line as a rule needs no apology. We have as yet heard but little of the working of the various base hospitals to which the patients have been finding their way, but that little has all been favourable as far as the hospitals have been concerned, though the railway transport has been poor and there has been a shortage of nurses. The absence of special correspondents, and the discreet silence enjoined upon all engaged in the war in any capacity, has caused us to depend largely for information upon the individual experiences of the sick or wounded who have returned from the front, and these experiences may entirely differ. One fortunate wounded man may be carried from the fighting line to immediate shelter, receive prompt first-aid, secure ready transport, and find himself in a base hospital in a comparatively few hours. He will be distinct in his praise of an organisation which has succeeded in his case so well. Within a mile or less of him circumstances might have made it completely impossible to clear the battlefield of wounded for many hours, and the story from such a scene would be very different. It is clear from the great activity that has been manifested recently in this direction that a shortage of nurses and ambulances has been recognised by the authorities, a situation which, we hope, is being promptly met.

◆

The Treatment of Streptococcal Infections.

THE morbid conditions produced by streptococci are so widespread and varied, and are frequently of such severe and dangerous character, that their effective treatment is a matter of the greatest practical importance. It must be confessed, however, that, in spite of laborious and carefully designed attempts to develop specific agents on the lines of other bacterio-therapeutic measures of proved efficacy to combat the streptococcus and its effects, these are in the main disappointing. This is more particularly the case in regard to the antistreptococcal sera, of which a considerable number have been prepared by different methods. Clinically these sera have been tried very widely, more especially in severe and generalised streptococcal infections. In some cases they appear to be useful, but in others they fail entirely. It was supposed that this might be due to the streptococcus used in preparing the antistreptococcal sera being of a different strain from that causing infection in the patient, consequently so-called polyvalent sera were prepared, many virulent strains of streptococci from different sources being used in their preparation. Although good reports have been obtained clinically from such sera, they have not fulfilled the expectations formed of them. We publish in this week's issue of THE LANCET an interesting paper by Dr. J. W. MCLEOD, in which the whole question of the value of antistreptococcal sera is critically discussed in the light of some experiments carried out with a streptococcus of high virulence for rabbits, and with a careful survey of the literature of the subject. It is a familiar clinical observation that recovery from many streptococcal infections does not confer any lasting degree of immunity upon the organism.

Dr. MCLEOD'S review of the scientific bacteriological analysis of antistreptococcal sera goes far to show that they can hardly be expected to be as efficacious as some of the well-known antitoxic and antibacterial sera for other organisms. It would appear that the actual antibodies present in antistreptococcal serum are very limited in character. That this serum has no bactericidal action has been demonstrated by numerous observers, and it is stated that virulent streptococci will grow in it. It has been supposed that some of the beneficial results which have been obtained with it are due to an anti-endotoxin, but there is no evidence of this, and many bacteriologists have shown that no antitoxin is present against the hæmolysin produced by the virulent strains of streptococci, which is closely associated, if not identical, with the actual endotoxin of the organism. Dr. MCLEOD states that three varieties of antibody have been found in antistreptococcal sera, of which two—viz., an amboceptor capable of absorbing complement and an agglutinin—are unimportant. The third antibody to which its chief protective power is attributed is an immune opsonin or bacteriotropin. Dr. MCLEOD comes to the conclusion that none of the antistreptococcal sera available for therapeutic purposes in man are likely to afford a supply of immune opsonin sufficient in quantity to alter the course of streptococcal infection in man. In his own experiments with rabbits he obtained slightly better results with normal heated horse serum than with antistreptococcal serum obtained from horses. It seems to us that these results, discouraging though they are, should not lead to the entire discarding of the procedure, still less to any slackening of the efforts to obtain a more potent variety of serum. It is generally admitted that these sera possess a high degree of protective power against streptococcal infections in mice, and therefore there are grounds for hoping that eventually some modification may be found in the mode of preparation which may render them more efficacious in man. Dr. MCLEOD is, however, of opinion that a more hopeful line of research is to try to find some artificial antibody to streptococcal toxin. Since it would seem that the attempts to induce passive immunity in man to streptococcal infections by means of sera have so far been disappointing, it is satisfactory to find that the experience with streptococcal vaccines is more encouraging, although this is difficult to reconcile with Dr. MCLEOD'S statement that cultures of streptococci killed by heat are of no value for immunising.

In the *Times* of Sept. 28th Sir ALMROTH WRIGHT, in the course of a plea for compulsory inoculation of the troops against typhoid fever, suggests that an antisepsis vaccine—i.e., a mixed streptococcus and staphylococcus vaccine—should be used as a prophylactic against the septic infection of wounds. He states that it is beyond controversy that these vaccines, if employed in time, almost invariably prevent and abort the corresponding septic infections. Autogenous and stock streptococcal vaccines have now been widely used in subacute and chronic infections with these organisms, and certainly with beneficial results, more especially in the cause of autogenous vaccines. With acute and generalised infections they obviously require to be given with great care and discrimination, but even here good results are on record.

Annotations.

"Ne quid nimis."

THE IDEAL PRACTITIONER.

THE attempt to portray a concrete embodiment of the ideal is always a fascinating pursuit. The portrait of the ideal medical practitioner has been essayed over and over again with greater or less success, and will doubtless continue to be drawn as long as medical practitioners shall exist. A recent felicitous effort in this direction is the inaugural address this year at the London (Royal Free Hospital) School of Medicine for Women, delivered by Miss Frances Ivens, honorary medical officer for diseases of women at the Liverpool Stanley Hospital. Naturally Miss Ivens laid particular stress on the special opportunities for the woman doctor. She expressed her conviction, one in which we agree with her, that before long there will be a decided public opinion that it is not right for an able-bodied young woman, in whatever station of life, to eat the bread of idleness or to allow her brains to atrophy for lack of use. The idea that a "gentleman" should be a person of "no occupation" has only of recent decades begun to die out, but already a healthy contempt for that idea is making itself generally felt. Public opinion is now beginning seriously to address itself to the question of a wider field of activity for women than our forefathers thought desirable or fitting. Miss Ivens enforces this teaching with a thought which the present European crisis must have brought to our minds forcibly, when she says that, "With the startling changes of fortune incidental to a great war, it will come home to many parents that a definite training is a much better insurance for a daughter than a monetary provision, which may be swept away in a financial crisis." Most of her suggestions are as sound and practical for the male medical student as for the female. We quite agree that it is useful to have prepared a definite plan of the use to which the student is intending to put her (or his) professional knowledge, however circumstances may vary it later. With such a plan concentration and coördination in study are more effectively maintained, while if circumstances do subsequently turn up which lead to a change of plan they will probably result from a later discovered special aptitude, which rightly cultivated will ensure success. That there is a field for the woman general practitioner has been unmistakably demonstrated by the revelation, through the operation of the Insurance Act, of a serious amount of special morbidity among the women of the poorer class. The results of this have been seen and faithfully dealt with to the best of their powers by medical men in general practice and on hospital staffs. But to the woman general practitioner in the nature of things will fall greater opportunities of preventing these morbid processes, or at least of recognising and arresting them before they have time to bring about the results that call for correction. Miss Ivens rightly lays stress on the importance of the gift of imagination, not only to glorify the common task, the daily round, but still more to enable the fortunate possessor to appreciate the position of others and so to realise the facts of life. Thus is acquired the invaluable gift of understanding, whereon depends the recognition of the human factor—the x of the biological equations of medicine. The possession of this quality not only helps in the conferring of the greatest good on the greatest number, but even, like mercy, it is twice blest—it blesseth him who understands as well as him who is understood. In no career, also, has the sense of humour a greater value than in medicine if rightly restrained. It is the oil that makes the machine run smoothly and with the least possible wear and tear from friction. Both these qualities play an important part, as Miss Ivens points out, in the composition of the ideal practitioner.

THE RÔLE OF TOBACCO IN THE WAR.

WE may surely brush aside much prejudice against the use of tobacco when we consider what a source of comfort it is to the sailor and soldier engaged in a nerve-racking campaign. With us at home it is a common experience that the smoking of a pipe, cigarette, or cigar does much to allay the restlessness and muscular irritability engendered by mental and physical fatigue. There can, indeed, be little doubt that tobacco fills an important place in the psycho-physiological affairs of the human race, and that the habit of smoking (which does not include over-indulgence and self-poisoning) does something to temper the intensity of the struggle. There are exceptions, of course, but smoking is a custom which has widely prevailed amongst men distinguished by their soundness of judgment and by their success in the worlds of art, science, and literature—men who have played a great part in solving the problems of existence in its many difficult details. Huxley once confessed that amongst his fellow students at the hospital he was exposed to considerable temptations to smoke, but on his essaying to acquire the habit he soon found himself on th floor. He gave it up for 40 years. On the occasion of a tour in Brittany, however, he found on a very wet and cold day a companion who looked so happy with his cigar before the warm fire within the inn that he thought he would try to smoke again. "And then I found myself a changed man. I found that I was in the position of a lamentable 'pervert,' although the person who led me astray was most distinguished and a late president of the British Association. From that day I date my ruin. For, from that day, whenever smoking is going on, you may be pretty sure that I join in it." To the soldier and the sailor in the present war, with his nervous system in a ceaseless state of tension from the dangers and excitement, tobacco must be a real solace and joy when he can find time for this well-earned indulgence. Abuse of the habit is, of course, pernicious, but to quote Huxley again: "Anyone could undertake to destroy himself with green tea or any other article of diet if carried to excess." The risk, at any rate, is as nothing compared with an abuse of alcohol. The hope is thoroughly justified that the soldier in the present campaign will be generously supplied with this indisputable creature comfort.

RADIUM IN THE TREATMENT OF UTERINE HÆMORRHAGE AND FIBROID TUMOURS.

IN the *Journal of the American Medical Association* of August 22nd is published an important paper on Radium in the Treatment of Uterine Hæmorrhage and Fibroid Tumours, which was read at the recent annual meeting of the association by Dr. Howard A. Kelly and Dr. C. F. Burnham. They point out that until recently the control of uterine hæmorrhage and the relief of pressure symptoms due to fibroid tumours was possible with certainty only by radical operations. In four groups of cases they have found radium treatment effective. The first group consists of cases of marked menorrhagia or metrorrhagia in adults with no disease of the pelvic organs except perhaps slight enlargement of the body of the uterus. The endometrium is microscopically normal. There were eight cases, and all the patients were suffering from anæmia, which had not yielded to palliative measures. Their ages varied from 27 to 44 years. Intra-uterine exposures of from 2 to 24 hours to radium in quantities varying from 60 to 268 milligrammes were given. In two cases the bleeding never recurred after the first exposure. In one case a second exposure was necessary. In the remaining five cases a normal period followed and was succeeded by complete amenorrhœa. Mild menopausal symptoms occurred in three cases, marked menopausal symptoms in one case, and no symptoms in four cases. All the patients finally reported themselves in good health. The second group includes most of the hæmorrhages which occur in young girls. In many the local condition is the same as in the first group, but in some it is similar to that in the third group (polypoid endometrium). There were five cases. In addition to the usual medicinal treatment all but one of the patients had been curetted. The amount of radium used varied from 12 to 60 milligrammes and the time of exposure from 5 to 24 hours. In three cases menstruation became normal; in one case amenorrhœa for two months was followed by menstruation, which was not excessive; and in the remaining case (where radium was applied through the abdominal wall) complete amenorrhœa with menopausal symptoms occurred. In the third group there were uterine hæmorrhages with polypoid growth of the endometrium. There were five cases. The amount of radium used varied from 30 to 100 milligrammes and the duration of treatment from 7 to 22 hours. With one exception all the patients were relieved at once by a single application. They were all anæmic and had resisted other forms of treatment. The fourth group consists of cases of fibroid tumours causing hæmorrhage or pressure symptoms. There were 21 cases. The amount of radium used varied from 30 to 560 milligrammes and the time from one and a half to 48 hours. In 16 complete amenorrhœa was induced. The tumours greatly diminished and in two cases disappeared. In these latter menstruation persisted. As to the mode of action of radium, it has been shown that the penetrating rays, like the X rays, destroy the primordial follicles of the ovaries, which determine menstruation. Hence most operators have endeavoured to concentrate the rays on the ovaries. Dr. Kelly and Dr. Burnham controvert this view that the beneficial effects of radium are produced on the uterus through the ovaries and believe that its action is direct. They point out that many fibroids grow after the menopause, and that in the two cases mentioned above the fibroid disappeared although menstruation persisted. They attribute the effect of radium to obliterative endo-arteritis, which is well known to occur almost invariably in the field of radiation. Their technique is as follows. The radium rays are filtered through glass, 0·5 mm. of platinum, 0·5 mm. of zinc foil, and 0·3 mm. of rubber. The apparatus, suitably shaped, is carefully introduced into the uterus. Cervical applications are less reliable. Before introducing the radium the patient is anæsthetised with nitrous oxide, thoroughly curetted, and examined carefully. In using the radium their plan is steadily to increase the amount while decreasing the time. Sometimes they reinforce the intra-uterine applications by abdominal radiation either with radium or the X rays.

THE ELECTROLYTIC BATH AND LEAD POISONING.

THE possibility of removing lead from the body by electrolysis in cases of plumbism is evidently not proven. In the papers which appear in our present issue Mr. Kenneth Goadby and Mr. W. H. F. Oxley both arrive at the conclusion that lead in demonstrable quantity cannot be removed by electrolysis from lead-bearing tissues under the usual conditions of the electrolytic baths recommended by Sir Thomas Oliver. These conclusions are supported by experiment and by argument. The experiments both upon animals and human beings were uniformly negative. The arguments are as follows. In the first place the movement of the lead ions is so slow that in the course of an application lasting for half an hour or even an hour any lead which lies at a distance from the surface of the body of one centimetre would not have time to reach the skin nor to reach the water of the bath nor the electrodes. In the second place, the proportion of lead ions to general tissue ions is so very small that almost the whole current would be conveyed by the latter, and the lead ions would be concerned only to such a minute extent in the conduction of the electricity that the weight of lead set in movement would be excessively small and could not be detected by chemical analysis. Thirdly, it appears that the lead in the tissues exists in a combination which keeps it out of action, so that it does not readily behave as an ion. This would be the case if it were in insoluble combination with the albumins of the body. An objection to this argument is that if the lead were truly insoluble it should be inert and unable to give rise to symptoms. But it may be the case that the lead is for the most part insoluble, and that the toxic symptoms are due to very small amounts of the metal which slowly pass from the insoluble into the soluble form. An interesting point comes out in one of Mr. Goadby's experiments—viz., the appearance of a lead deposit at the anode of the cell. Though this might be thought odd, it is not unusual. Lead may appear at either pole of an electrolytic cell. At the kathode it is deposited as metallic lead, but under certain conditions it may appear at the anode in the form of lead peroxide.

DISPOSAL OF EXCRETA IN CAMP AND ON FIELD SERVICE.

THE question of camp sanitation is of great importance at the present time, when all over the country bodies of men are collected together for the purposes of military training, being accommodated generally either under canvas or in buildings temporarily used for the purpose, and not provided with the ordinary arrangements for removal and disposal of excreta. Under these circumstances, temporary expedients are generally adopted, more or less unsatisfactory, unless considerable outlay is incurred on laying out land for sewage treatment or on a drainage system for removal to a distance. By the joint investigations and inventiveness of Dr. Myer Coplans and Mr. James Menzies a method has been evolved which appears to satisfy requirements effectually and economically. The apparatus consists of: (1) a partitioned chamber for reception of excreta; (2) a condenser; and (3) a receptable for the condensed products. The tank into which the excreta (mixed fæces and urine) are introduced is cylindrical in shape and divided into several sections by horizontal partitions. The sewage is poured in at the top through a hopper and broken up by a revolving comb; it passes on from above downwards through the successive partitions, being exposed all the time to a high temperature. As a result there ensues complete disintegration. The solid residue comes out at the bottom carbonised into charcoal; the volatilised products are led through a condenser and received into a chamber, where they settle out into (1) a heavy ammoniacal liquor, (2) a layer of oil, and (3) gaseous products. These last are piped off to a burner, where their combustion provides the heat required to produce the disintegrating action on the sewage that takes place in the partitioned chamber. The ammoniacal liquor forming the lowest layer in the receiver contains pyridine bases, which are of value as an insecticide (against flies, &c.) and as a bactericide (against B. typhosus, &c.). The layer of oil is collected and used as fluid for working the motor that actuates the revolving comb or scraper in the cylinder first mentioned. The solid carbonised residue is practically pure carbon, which may be used as fuel or for many other purposes. In this method of treatment it appears that by means of an ingenious practical application of scientific principles, long known, but not hitherto utilised so completely or so successfully as in the apparatus under consideration, Mr. Menzies and Dr. Coplans have not only been successful in showing how much value lies in the excretory products (a fact often logically proved before now), but have also demonstrated that these products may be rendered innocuous and disposed of at a very minimum of cost, or even at no cost at all; it is quite possible that the residual charcoal may come to be a source of profit. At any rate, it seems proved that the working expenses are covered—that is, that the installation pays for itself. The fact of the apparatus being self-contained and self-supporting —viz.: (1) that the heat required for the destructive distillation of the excreta is provided by the gas which is set free; and (2) that the petroleum oil for running the motor is also obtained from the results of the same distillation—distinguishes it from all other chemical processes or methods of disinfection depending on heat. It is stated that no fuel is required at all beyond lighting up at the commencement of working. That an insecticide and bactericide should be obtainable from the condensation liquor is also much in favour of this method, if in practice it can be recovered without difficulty. In camp life such a substance would be most useful for the destruction of flies, fleas, and vermin generally, as well as for its more important disinfectant applications to contagious pathogenic material. The apparatus is installed at the Wimbledon sewage works, where it is in full working order, and, we understand, is shortly to be brought into practical application on a large scale by the War Office.

THE MEDICAL SOCIETY OF LONDON.

THE 142nd session of the Medical Society of London will open on Monday evening, Oct. 12th, when the annual general meeting will be held at 8 o'clock, and the incoming President, Sir John Bland-Sutton, will deliver his introductory address at 8.30. The Lettsomian lectures for 1915 will be delivered by Mr. Arthur E. Barker on Feb. 1st and 15th and March 1st; the anniversary dinner will take place on March 10th; and the annual oration will be delivered by Sir William Osler on May 17th. The joint honorary secretaries for the ensuing session are Mr. George E. Gask and Dr. Herbert French. The first discussion will be held on Oct. 26th, and the subject chosen is the operative treatment of tumours of the cæcum and colon, especially in relation to immediate resection, colostomy combined with secondary resection, and short circuiting. The openers will be Mr. H. J. Waring, Mr. James Sherren, and Mr. Lawrie McGavin. The subject of the discussion on Nov. 23rd is tumours of the pituitary body.

MENTAL DISEASES IN SWITZERLAND.

OUR special correspondent in Zürich draws attention to a statistical treatise on mental disease in Switzerland which has just been published by Dr. A. Koller, resident physician in the Cantonal Asylum at Herisau. As there is no official registration of mental cases in Switzerland, Dr. Koller collected the number of cases admitted in all the public asylums of Switzerland, 30 in number, and the rapid increase of mental disease is visible from the following figures :—

Date.	Number of patients.	Percentage of total population.
1875	2983	1·09
1885	3909	1·36
1895	5669	1·82
1900	7099	2·14
1910	9366	2·51

In 1910 probably 700–800 patients were in private asylums, and doubtlessly double that number in families, but exact data were not obtainable. The number of patients in asylums has, it appears, more than trebled in 35 years, whilst the increase of population was only about 40 per cent. Mentally deficient children and epileptics are not included in these statistics. It is noteworthy that in 1845, as far as figures are available, there seem to have been only 600 mental patients in Switzerland, equivalent to 0·2 per cent. of the population, but neither the figures nor the diagnoses can be worth much.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: MUSEUM DEMONSTRATIONS.

A SERIES of demonstrations of specimens in the Museum of the Royal College of Surgeons of England will shortly be given. The demonstrations are intended for advanced students and medical practitioners, and will take place in the theatre of the College in Lincoln's Inn-fields. The dates and subjects of the demonstrations are as follows: Friday, Oct. 16th, Professor Arthur Keith, Specimens illustrating Gunshot Injuries of the Head—Ancient and Modern. Monday, Oct. 19th, Mr. S. G. Shattock, Specimens illustrating Carcinoma. Wednesday, Oct. 21st, Mr. J. F. Colyer, Specimens of Injuries to the Jaws and Teeth of Animals. Friday, Oct. 23rd, Professor Keith, Specimens illustrating Gunshot Injuries of the Limbs. Monday, Oct. 26th, Mr. Shattock, Specimens illustrating Tuberculosis. Wednesday, Oct. 28th, Mr. Colyer, Specimens of Dento-alveolar Abscess and Dental Cyst. Friday, Oct. 30th, Professor Keith, Gunshot Injuries of the Thorax and Abdomen. Monday, Nov. 2nd, Mr. Shattock, Specimens illustrating Repair. Professor Keith and Mr. Shattock will demonstrate at 5 P.M. each day and Mr. Colyer at 5.30 P.M.

TESTICLE TRANSPLANTATION FROM THE DEAD TO LIVING BODY.

A MOST striking therapeutic procedure which apparently has met with remarkable success is reported in the *New York Medical Journal* (1914, c., 67) by Dr. G. Frank Lydston. It consisted, briefly, in the transplantation of a testicle from a man who had recently died into the scrotum of a second individual. The object of this proceeding was to try to effect relief for extensive psoriasis; the result was certainly beneficial. The writer is of opinion "that perversion of nutrition, primarily due, perhaps, to an aberration of quality and quantity of internal secretion—of the sex or other glands—underlay skin lesions of the class in question." His ideas, as foreshadowed in this paper, also extend to advocating the value of gland implantation to other conditions, such as diabetes, tuberculosis, and even carcinoma. The immediate case referred to here is that of a man aged 53, a hard drinker and gourmand; no syphilis; a history of two tappings for ascites six years previously, when he was supposed to have cirrhosis of the liver. His present condition showed a large and hard liver, and much ascites which was successfully tapped and six gallons of fluid removed. There was present also some evidence of a tumour mass in the abdomen. As regards the psoriasis, it extended on the back of the arms and forearms, the front of the right leg, the buttocks, the lumbar region, and the back. The patches were large and the patient had had them for many years. The operation consisted in the transplantation of a testicle—with the epididymis excised—removed from an apparently healthy subject about 21 years of age, dead 30 hours before from contact with a live wire. Operation was performed 10 hours after removal of the testis—that is, 40 hours afte death. The post-operative course was uneventfu On the third day after the implantation improvement was noted in the psoriasis, and eight days after the operation the lesions were so improved that they could scarcely be recognised as psoriasis. Betterment of the general condition of the patient also followed, though there was some evidence of a further accumulation of fluid.

THE National Health Insurance Commission have issued a Memorandum to Insurance Committees on the terms and conditions of medical service for next year, altering the arrangements for medical certificates and the dates for the revision of doctors' and chemists' agreements.

AMBULANCE WORK IN FRANCE.

BY JAMES DONELAN, M.CH., M.B. R.U.I.,

CHEVALIER OF THE CROWN OF ITALY; SURGEON TO THE THROAT DEPARTMENT OF THE ITALIAN HOSPITAL, LONDON.

IN accordance with the invitation of the Editor of THE LANCET I send the following notes of such observations as I have had an opportunity of making during my recent visit to some of the ambulances in the western portion of the seat of war in France. I should like to point out most distinctly that the ambulances I visited or in which I did some surgical work were only those in relation to the French army. The only British soldiers I came into contact with were a small party who had lost their way, one of whom had a bullet wound in the scalp, and some of our Army Service Corps who brought a comrade to the ambulance of which I had temporary charge at Crépy-en-Valois. This man had fallen under a train, and his left forearm and arm were so crushed that I had to amputate near the shoulder. In view of the naturally great interest in the arrangement for our own wounded I have requested a surgical colleague now in France to visit the line of country through which they are being sent down.[1]

Arrangements for Dealing with the Wounded.

Any consideration of the ambulance arrangements must keep in view three factors: the gigantic nature of the conflict, the unprecedentedly large numbers of wounded, and the small opportunities of picking up the more severe cases beyond the trenches unless a decided advance has been gained. To some extent German firing on Red Cross workers and flags of truce for collection of wounded has also prevented the immediate assistance hoped for in a war between civilised armies.

Though the large majority of those who reach such base hospitals as Dieppe have bullet wounds of soft parts from which they as a rule rapidly recover, there is a good number of cases of wounds of cavities which have taken a serious turn since their arrival. During my journey up in the first train taking back refugees from the districts immediately south of the Aisne we had a very long halt while strengthening a trestle bridge that had been placed instead of one destroyed by the retreating enemy. No less than five long trains full of wounded French and one British passed us. There must have been between five and six thousand in all. The vast majority could be seen sitting up; many were looking out of the windows and waved their hands to us. On the other hand, the impression must be guarded against that this represents anything like the real picture. Owing to the desperate character of most of the fighting, its continuance, and the fact that commanders have had to check the excessive zeal of the medical services in the interests of the rest of the army, I am assured that a man severely wounded, as by shell fire, in the early part of the day has a very poor chance of being picked up outside the trenches before evening unless some advance is made or some lull takes place in the firing. This accounts to a large extent for the comparatively slight character of the wounds of the majority of those who reach the base hospitals.

---

[1] We hope to publish a report from the well-known surgeon here indicated, but the vagaries of the French mails forbid any promise.—ED. L.

The method followed by both the British and the French armies is to send all cases that appear to be able to bear the journey from the field dressing stations as rapidly as possible to the large hospitals in Paris, Rouen, and other cities. Those who prove unable to bear the journey in the train are discharged on the way where there happens to be a hospital. At a station on the way to Crépy I was shown a building in which were the bodies of three French soldiers who had died in the train. The more severely injured are, as far as possible, sent by motor ambulances to the nearer collecting hospitals or even to Paris if it appears practicable.

The Nature of the Injuries.

A reference to some injuries I have seen may be of interest. Most of them were bullet wounds. The orifice of entry of the German bullet just admits an ordinary cedar pencil, and in soft parts that of exit is hardly larger. Where the missile has been deflected by bone or other dense tissue it may continue its course sideways, causing much destruction. Since my return my attention has been called to the remarks of Mr. Selous on this subject, and I am inclined to reconsider my view of the case at Crépy mentioned by me in last week's issue. It is quite possible that even a non-expanding bullet deflected from its course may have caused the destruction of the right side of the face there described. Unless expanding bullets are actually found in relation to such wounds, in view of Mr. Selous's remarks their use must be regarded as not proven. I do not think the German authorities systematically issue dum-dums, though there is ground for believing that individual soldiers, or even small parties of them, may sometimes convert ordinary bullets into expanding ones by suitable filing. I was also shown some skiagrams in which bullets had extensively splintered long bones, finally lodging in the articulations of hip and shoulder. In one the opposite course was taken. Entering the front of the femur it had run down the hollow of the bone, finally lodging in the tibia. Another showed a shrapnell ball fixed between the tibia and the femur.

One patient was shot immediately below the left auditory meatus, the missile knocking out the opposite upper canine and bicuspid. When one thinks of the relations to its course it is remarkable that he was discharged convalescent on the fourteenth day. The more serious bullet wounds were those in which there was splintering of long bones, and injuries to head, chest, or abdomen. A German prisoner under my care had been shot from behind, it was said by his own officer, the bullet passing under the scalp and ploughing the right parietal bone for about an inch. The inner table did not appear to be injured and he did very well for about a week, but just before I left he had developed encephalitis.

As might be expected in an old agricultural country, tetanus is very rife. I should not like to mention the proportion in the cases I saw as there were not sufficient to form a general estimate. The proportion is, I am assured, very high, especially in cases of shell wounds of the lower extremities. Antitetanic serum is extensively used, but, as might be expected, has little influence in developed cases, and its use as a prophylactic remains yet to be more conclusively established. I had another German patient who died from tetanus on the fifteenth or seventeenth day after being hit; he underwent amputation below the knee, and secondary amputation for spreading gangrene at mid-thigh. He was one of the German prisoners whom their own surgeon did not visit on the occasion when he came to report on the wounds of the British and French prisoners during the German occupation.

On the whole the general impression I received was that though surgeons were much needed a week or two ago in some of the stations near the front the arrangements on the whole were admirable, and everyone was doing his and her duty with the utmost zeal and self-sacrifice. People whose ideas of war and ambulance work are derived from witnessing mock combats at Olympia and elsewhere should not be at all ready to criticise the real thing, when enacted on the most gigantic scale and under the most terrible circumstances in the history of the world.

DIEPPE AS A MILITARY HOSPITAL BASE.

BY W. KNOWSLEY SIBLEY, M.A., M.D. CANTAB.

THE following notes founded on a recent visit to Dieppe may prove of interest to readers of THE LANCET at the present time.

The French military medical authorities have placed as many of their base hospitals on the sea coast as possible, the opinion being that the fresh air of the seaside, together with the comparative absence of flies and mosquitoes, puts the wounded under the most favourable circumstances for their recovery.

The delightful French watering place, Dieppe—so well known to many English people who appreciate the beauties of the coast of Normandy, and usually so gay and full of life—has been completely transformed into one huge base hospital for the wounded soldiers, French, German, and a few English. The Casino, the College, and nearly all the large hotels no longer cater for the pleasures and luxuries of the rich, but are full of the wounded, and bear testimony to man's marvellous inventions for the destruction of the lives and limbs of his fellow creatures.

The French military surgeon in command of all the Government Hospitals in Dieppe is Major Doctor Gauillard, of Rouen, who is attached to the 12th Chasseurs, and I had the honour of accompanying him round the largest of his hospitals on Sunday last.

The College and all the large hotels on the sea front, such as the Grand, the Métropole, the Paris, and the Beau Rivage, have been hurriedly transformed into hospitals, and contain between them some 1200 wounded, and many more are expected.

Fever cases are sent to the Dieppe Hospital. Some two or three weeks ago there was a panic in Dieppe, as the Germans were expected to enter the town, which is a "ville ouverte." At 1 o'clock at night Dr. Gauillard received instructions from headquarters to remove the whole of his wounded and the hospital equipment immediately by rail to Havre. Before morning they were all, some 400 in number, on the train. On arrival at Havre they received word to cross the Seine to Trouville, and on arrival there they were sent on to Deauville, where the Casino was rapidly prepared for their reception.

At the moment the largest number of cases are in the Collège de Dieppe, where some 250 beds are installed, 40 being occupied by wounded Germans, whose condition is much less favourable than that of our allies, as they have all been left much longer on the battlefield, and apart from their wounds, which are more severe, they are very dirty when first received into hospital. Ordinary bullet wounds, unless they have penetrated some vital organ, are not usually very serious; even if they have struck bone they generally pass right through and but rarely produce a fracture. Wounds by shrapnel, on the other hand, nearly always suppurate, because some piece of clothing has been carried in with them.

Chloroform is only administered for major operations, and the probing and cutting down for the extraction of bullets is performed under the very partial anæsthesia of eucaine and adrenalin. Fresh batches of wounded arrive by train, always in the middle of the night. The surgeons go round from bed to bed, an *infirmière* carrying a bowl to receive the bullets as they are removed, and the monotonous click of lead falling into the bowl continues until this receptacle is filled, when another takes its place.

An interesting case was that of a man who had received a bullet in the side of his nose, and a skiagram showed it to be lying just above the inner end of the clavicle. Another was that of a young man who some ten days previously had received a shock from a bursting shell which had killed his comrade but had not touched him; there was not even a bruise to be found on any part of his head or body, but he had completely lost his memory and speech, and was in a condition of amentia. I saw one marked case of tetanus and two suspicious ones, and three cases of septic pneumonia. It was suggested that the tetanus was conveyed from the straw on which so many of the wounded are placed as they are being removed to the hospitals. The mortality among the wounded has not been very heavy, and so far there has been almost a complete absence of general illness among the French troops.

The College and all the larger of the hotels are under the military, the Casino and some others under the Croix Rouge, where la Baronne de la Borgue-Noguez superintends the nursing.

At the Casino the concert hall and ball-room have been transformed into wards, so also have the adjacent reception-rooms. Here at the time of our visit the majority of the cases were sitting in the Restaurant de Casino enjoying an excellent *déjeuner*. The beds of those who were unable to be up had been carried into the gardens and placed by the tennis courts, with temporary awning adjusted over the heads of the beds as a protection against the sun's rays. This building makes an excellent summer hospital, but as there are no means of heating, it is difficult to see what will happen in the winter months.

Each hospital has a surgeon appointed in charge, and the nursing is performed by *infirmières*, who are chiefly ladies living in the chalets about who have volunteered their services and do what they can for the poor soldiers. A few are capable women who have had some nursing experience, and at the moment there are two English ladies who are fully trained nurses, the one at Pourville and the other at the Grand Hotel, Dieppe, but the majority are absolutely untrained and inexperienced. They nearly all live in their own residences, and go to the wards in the morning, leaving in the evening. Thus at night the hospitals are left to take care of themselves, of which state of affairs the less said the better.

A few trained English nurses, who can speak French, would be of great assistance in Dieppe at the present time, and would be gladly welcomed by the authorities.

I must thank Dr. Gauillard for his kindness and courtesy and the trouble he took in showing and explaining everything to me, and also among his assistants my special thanks are due to Dr. Dupont, of the Métropole; Dr. Toutbon and Dr. Carro, of the College; Dr. Thivet, of Pourville; Dr. Tripier, of the Plage; Dr. Circin, of Beau-Rivage; and Dr. David.

Sept. 29th, 1914.

THE CLAIMS OF BRITISH SPAS.

(Continued from p. 804.)

II.—BUXTON.

THE facilities for hydropathic treatment at Buxton have been considerably increased during recent years. The waters at this beautifully situated health resort fall clearly into a group of well-known therapeutic reputation abroad. To begin with, they are thermal, the temperature (82° F.) being an agreeable one for immediate use, and next as regards actual chemical composition, the total mineral constituents are 27·32 grains per gallon, the chief being the carbonates of calcium and magnesium (20 grains per gallon) and common salt. The water gives off a quantity of gas, consisting of nitrogen, helium, argon, and other rare gases, the presence of which, coupled with the natural heat of the water, commonly connotes radio-activity. These observed facts mean that in Buxton water we have a counterpart of the waters of Wildbad, Schlangenbad, and Gastein which can claim no further attributes.

Considerable attention has been directed in recent years to the radio-activity of the Buxton thermal waters, and it has been found that the amount of radium expressed in millionths of a milligramme in radio-active equilibrium with the emanation actually present per litre of gas or water is in the former case 10·9 and in the latter 1·2. It is pointed out that the waters of Buxton and Bath at the time of emerging from their source contain radium emanation to the extent of 1·2 and 1·7 respectively, and that in spite of the fact that the continental waters (e.g., Gastein and Plombières) show much higher figures there is no evidence that these possess a greater therapeutic value. Radio-activity alone would appear, therefore, not to offer a complete explanation of therapeutic value, for the doubt is expressed whether any spa in the world can show such a record of successful treatment as is contained in the official records of the Devonshire Hospital and the Buxton Bath Charity. Possibly the degree of ionisation of the saline constituents is much greater in the presence of emanation. Considerable value is now being attached to the action of calcium in metabolic processes, and the presence of this element in an ionised form may account for the therapeutic superiority of Buxton water over, say, that of Gastein, which is much more strongly radio-active, but which contains no minerals to speak of at all.

The hydropathic equipment at Buxton is very complete, balneological, electrical, and accessory, and no less than 87 methods of treatment are available. The following is an epitome of the diseases which are benefited by treatment at Buxton according to the experience of the medical practitioners there.

In gout the baths and waters are largely and successfully used in the treatment of this disease, and are generally applicable to its diversified manifestations as well as to affections depending upon uric acid diathesis. Skin diseases of gouty origin, and especially gouty eczema, are benefited by both internal and external treatment.

In articular and muscular affections, whether the result of rheumatic fever or gradually supervening on exposure to cold or damp, the baths and waters are beneficial. In recent and subacute stages the treatment must be gentle and tentative; in chronic conditions more vigorous and stimulating applications are required. Osteo-arthritis and rheumatoid arthritis are often relieved, and the disease may become stationary or retarded under a judicious course of balneotherapy combined with the climatic advantages of the place, while many cases of septic arthritis are permanently benefited. The chronic forms and later stages are often improved to a considerable degree, and stiff joints rendered more supple and free from pain.

Glycosuria and early diabetes are said to benefit greatly by the use of Buxton water. Complete disappearance of sugar is often observed as the result of treatment, especially in cases of gouty origin.

For the relief of high arterial tension the Bourbon-Lancy treatment and the radio-oxygen baths are especially designed, but observations made upon a large number of cases have shown that a course of drinking the water, of bathing, and especially of douche massage baths, results in a very marked fall of tension when this is unduly high.

Patients suffering from the early stages of arteriosclerosis do well under an annual treatment at Buxton owing again to elimination of toxins, the general treatment helping to maintain the elasticity of the blood-vessels. Some diseases of the nervous system, and especially those of a functional character, derive great benefit from Buxton methods. Tropical and subtropical diseases in their later stages and malarial conditions are also improved by baths and climatic treatment.

In heart diseases associated with gout or rheumatism the administration of the baths requires caution and experience. There are favourable conditions for treatment of these diseases by the Nauheim effervescent bath, and a large number of patients undergo this treatment with excellent results. Digestive disorders are often benefited by the stimulating effect of the baths and climate. The fact remains whether we subscribe or no to the explanation that the radio-active water helps these cases by increasing ferment activity. In colitis the Plombières douche is given with great success.

Lastly, anæmia when supervening on some acute condition, or the result of some rheumatic affection, yields well under treatment, and generally speaking the Buxton treatment, in which climate is an important factor, is adapted to conditions of weakness attending chronic disease.

In regard to contra-indications the waters and baths are not recommended when there is advanced heart or advanced kidney disease, but there can be no absolute rule for individual cases, and the extent or restrictions of the employment of the baths and waters can be best determined by those familiar with their actions and uses.

Buxton enjoys a bracing atmosphere, the town being on the highest urban site in England, at an altitude of 1000 feet above sea level. There can be little doubt that healthy climatic conditions are an important adjunct to hydropathic measures, and the success of Buxton as a balneotherapeutic station has probably depended largely upon a lucky partnership of healing air with healing waters. The surrounding scenery of the Peak is notorious for beauty, while as to amusements and recreations the history of Buxton as a leading watering place has been long, and those responsible have learned that social attractions which usefully divert from hydropathic régime will contribute in no small degree to the patient's convalescence.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Surgeon: L. C. Rowan-Robinson to the *Victory*, additional. Temporary Surgeons: H. R. Phillips to the *Soudan* (Hospital Ship I.); B. J. Brewitt to the *Pembroke*, for R.N. Barracks; T. Beaton to the *Mars*; C. H. Masson, M. H. de J. Harper, R. H. Knowles, A. D. E. Bayliss, and T. Norman, all to the *Pembroke*, additional; F. G. L. Scott to the *Wildfire*, additional; A. F. Adamson and T. R. G. Melrose, both to the *Victory*; R. W. Townley and P. M. Grundy, both to the *Vivid*, all for disposal; E. F. Fisher, L. R. Warburton, H. J. McCaw, and H. G. Parker, all to the *Vivid*, additional, for Plymouth Hospital, additional; T. S. Bradburn, and W. R. E. Unthank and E. M. Thomson, both to the *Victory*, additional, for Haslar Hospital.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon James Keogh Murphy to be Staff-Surgeon (dated Sept. 25th, 1914.

ARMY MEDICAL SERVICE.

Colonel George F. A. Harris, C.S.I., is appointed an Honorary Surgeon to the King, vice Surgeon-General A. M. Crofts, C.I.E. (dated May 25th, 1914).

ROYAL ARMY MEDICAL CORPS.

Major John D. Alexander to be Lieutenant-Colonel (dated August 31st, 1914).

The undermentioned have been granted the temporary rank of Lieutenant:—John Frederick Gill, Edgar Ashby, Ernest Edward Scott Joseph Galbraith, William Thomas Hessel, Thomas Harold Pettit, James Bruce Anderson, Frederick William Robinson, Arthur Theodore Todd, Thomas Edmund Ashdown Carr, George Samuel Sims, James George Blyth Coleman, and Frank Whitby (dated August 5th, 1914). George Alfred Gates (dated Sept. 12th, 1914). Gwilym James (dated Sept. 14th, 1914). Samuel Christopher Reeve Flaxman, James Mill Renton, and Allan Coulter Hancock (dated Sept. 15th, 1914). Frederick Sadleir Brereton, late Captain R.A.M.C., John McIntosh Morgan, James McTurk, Herbert Francis Woolfenden, James Kirker, John Stanley Lloyd, William Neave Kingsbury, George William Lloyd, Herbert Jack Rawson, Ernest Stratford, Richard Reid Kirkwood Paton, Claude Hebden Barker Booth, George Ernest Beaumont, Patrick Cagney, James David Grahame Stewart, Edgar Fletcher Edmunds, Stanley Parke Stoker, Harold Garnett Janion, Russell Facey Wilkinson, Oliver Cuff Link, Ernest Edwin Holden, Eustace Couper Black, William Griffith, and Charles St. Aubyn Vivian (dated Sept. 16th, 1914). Richard Frank Bolt, Daniel Stirling Cooper, William Claude Horton, Cecil Meredyth Jones, Richard Bertram Johnson, Alfred Charles Jepson, William Hilton Parry, Hugh Pierce, James Henry Paterson, and Henry Cecil Douglas Miller (dated Sept. 17th, 1914). Henry Anderson Lunn and James Wilson (dated Sept. 18th, 1914). Frederick Buick McCarter, Valentine Cleeve Martyn, David Young Buchanan, Emanuel Prinski Scott, Edward Leonard Puddicombe, Edward Hamilton, Murdoch Mann Rodger, James Randolph Gyllencrentz, George Arthur Spear, Henry Constantine Woodyatt, William Ainslie, Albert Turner, Ralph George Dainty, Captain Ryder Percival Nash, 2nd Eastern General Hospital, R.A.M.C., T.F., George Victor Bakewell, and Frederick Francis Middleweek (dated Sept. 19th, 1914). Gideon Walker, John Ferguson Smith, William Moodie, and Thomas Howard Body (dated Sept. 20th, 1914). Andrew Currie, Robert Hannah, Frederick George Sharpe, Stanley Ritson, Alexander Lindsay, William Henry Sutcliffe, Roy Warren Russell-Jones, Leslie Henderson Skene, Trevor Hamilton Wilkins, Ievan Herbert Powell, Basil Eustace Moss, Alexander Lindsay Aymer, Lewis Hay Frederick Thatcher, Isaac Bertram D'Olier, and Octavius de Burgh Marsh (dated Sept. 21st, 1914). Percy Gully and Bartholomew James Hackett (dated Sept. 23rd, 1914). Rudolph George Abercrombie Cornelius Alexander O'Driscoll, John Samuel Williamson, Herman Watson Webb, Sydney Hartley Hay, Robert Marshall, Arthur Arbuthnot Straton, William Harold Raphael McCarter, Charles Rees Smith, Samuel Gurney Dixon, David Joseph Mulholland, Alexander James Will, William Rankin, Basil Newman Murphy, Alan Gabriel Bodman, Reginald Beaumont Heygate, George Francis Hardy, Hugh Fleming Warwick, William Walls Waller, Reginald Charles Verley, Alexander Michael Ross, the Honourable Lennox Hannay Lindley, and Lionel Tomas Wells (dated Sept. 22nd, 1914). Eric Martyn-Clark, Christopher Charles Court, George D'Rastrik Carr, and Elston Herman Lawson (dated Sept. 23rd, 1914). Elliott Thornton Glenny and James Leitch Wilson (dated Sept. 24th, 1914). Daniel Thomas Henry Croly (dated Sept. 25th, 1914). Ernest Richard Gordon Greville, Charles Edward Redman, and William Edward Kyte Coles (dated Sept. 26th, 1914). John Inchbald Johnson, Alexander Croydon Palmer, and Alan Herrenden Birks (dated Sept. 28th, 1914).

Lieutenant Edward M. Thomson relinquishes his temporary commission (dated Sept. 19th, 1914).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Captain George Lane to be Major (dated Sept. 30th, 1914). Supernumerary Captain George Lane is restored to the Establishment (dated Sept. 7th, 1914).

The undermentioned cadets and ex-cadets of the Officers Training Corps to be Lieutenants (on probation):—Alan Francis Grimbly (dated August 6th, 1914). William Kealty Campbell and John Herd Beverland (dated August 8th, 1914.) Kenneth Duncan Murchison and Hugh George Trayer (dated August 16th, 1914). Albert William Darnley Magee (dated August 21st, 1914). Edward Richardson Lovell and William Ferguson Wood (dated August 24th, 1914). William Roy Blore (dated Sept. 1st, 1914). Joseph Bannister Williamson (dated Sept. 2nd, 1914). Peter Francis Ward, Wyndham Williams, and John Pritt Jackson (dated Sept. 3rd, 1914). John Brumwell, John Kew Ritchie Landells, John Clark Pyper, and James Lanigan (dated Sept. 6th, 1914). Francis Albert Eley Crew, David Stewart, and Raymond Fearle Pinson (dated Sept. 7th, 1914). Eric Watson Williams, William John Adie, Walter James Fairlie Craig, and Reginald Oliver Eades (dated Sept. 8th, 1914). Ian Campbell Mackay, Rudolph Albert Peters, and Richard Andrew Austin (dated Sept. 9th, 1914). William Somerset Birch (dated Sept. 10th, 1914). George Stanton, William Johnson, Adiel Elad Hazael Reid, John Hawkes Pendered, Arthur Leonard Shearwood, Ralph Reakes Thompson, and Cyril Ratcliffe Sandiford (dated Sept. 11th, 1914). Samuel Walter Maslem Jones and Joseph Herbert Bayley (dated Sept. 12th, 1914). Ernest Marshall Cowell and Geoffrey Norman Smyth (dated Sept. 14th, 1914). Reginald Salisbury Woods (dated Sept. 15th, 1914).

The undermentioned to be Lieutenants (on probation):—Richard Arthur Stewart (dated August 30th, 1914). Frederick Arnot Bearn and Alexander James Ewing (dated Sept. 1st, 1914). Harold Emerson Rose and Richard Naunton Ouseley Moynan (dated Sept. 2nd, 1914). Edward Hesketh Roberts, Morgan Joseph Bernard Francis Burke-Kennedy, John Victor Livingstone Grant, John Woodruff Craw, Francis Balkwill, and William Wyllie McNaught (dated Sept. 3rd, 1914). Edmund Britten Jones, James Vallance, Joseph Andrew Lawther Wilson, Thomas MacKinlay Miller, George Guthrie Marshall, and Mark Avent (dated Sept. 4th, 1914). Geoffrey Ward Wood and Robert Ernest Bell (dated Sept. 5th, 1914). Leonard Foster Browne, John Prince Stallard, and Ernest Talbot (dated Sept. 6th, 1914). Timothy Francis Hegerty, Douglas Gordon Evans, Charles Cochrane Iles, and William Stanley Haydock (dated Sept. 7th, 1914). Frank Griffith (dated Sept. 8th, 1914). Alfred Joseph Clark, Geoffrey Marshall, and Bernard Grellier (dated Sept. 9th, 1914). Cuthbert Hastings Attenborough, Harold James Storrs Morton, Reginald Heber Leigh, Edward Sancton Walls, George Martin Chapman, Alfred Maurice Thompson, and James Davidson (dated Sept. 10th, 1914). James Bethune Scott, John Phimister Mitchell, Ronald Gordon John McEntire, Edward Claude Linton, John Prosser Davies, David William John, and George Robert Bruce (dated Sept. 11th, 1914). Patrick McDonnell, Bernard Murphy, and Donald Aucutt (dated Sept. 12th, 1914). William Henry Wood (dated Sept. 13th, 1914). Peter Warwick Ransom, Kenneth Biggs, John Berchmanns Minch, and Henry Alphonsus Harbison (dated Sept. 15th, 1914). Frank Robinson Kerr, Cyril Popham, David Sutherland Badenoch, Bertram Shires, Oriel John O'Brien O'Hanlon, Archibald Wilson, and William Goodman Shakespeare (dated Sept. 16th, 1914). Joseph Illingworth Lawson, William Campbell Fleischmann, Hugo Rudolph Friedlander, and Cassidy de Wet Gibb (dated Sept. 17th, 1914).

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st East Anglian Field Ambulance:—The undermentioned Captains to be Majors (dated Sept. 26th, 1914): Gerald Moore Hetherington and Octavius Roberts Ennion.

1st Home Counties Field Ambulance: Lieutenant Thomas Henry Peyton to be Captain (dated Sept. 3rd, 1914).

2nd Welsh Field Ambulance: Captain Charles R. White to be Major (dated August 5th, 1914). Lieutenant Arthur C. Devereux to be Captain (dated August 5th, 1914).

3rd Lowland Field Ambulance: Archibald Cotterell McMaster to be Lieutenant (dated August 10th, 1914). James Abbey Henderson to be Lieutenant (dated August 10th, 1914).

1st Northumbrian Field Ambulance: Captain James P. Milne to be Major (dated 22nd August, 1914).

5th Southern General Hospital: Major John Kyffin to be Lieutenant-Colonel (dated Sept. 5th, 1914).

2nd West Riding Field Ambulance: Wallace Wright Adamson to be Lieutenant (dated Sept. 10th, 1914).

3rd Northumbrian Field Ambulance: The undermentioned Captains to be Majors: Percy R. Ash and William A. Thompson (dated Sept. 10th, 1914). Arthur Charles Mears Savage to be Lieutenant (dated June 22nd, 1914).

1st South-Western Mounted Brigade Field Ambulance: Lieutenant William C. Hodges is absorbed into the establishment (dated Sept. 16th, 1914).

1st Welsh Field Ambulance: Lieutenant-Colonel John William Davies resigns his commission, and is granted permission to retain his rank and wear the prescribed uniform (dated Sept. 30th, 1914). Major Evelyn John Robert Evatt, from the Unattached List for the Territorial Force, to be Major (dated Sept. 30th, 1914).

2nd Highland Field Ambulance: Hawtrey William Browne to be Lieutenant (dated Sept. 30th, 1914).

3rd East Lancashire Field Ambulance: Quartermaster and Honorary Lieutenant James E. H. Anderton, from East Lancashire Clearing Hospital, to be Quartermaster, with the honorary rank of Lieutenant (dated Sept. 30th, 1914).

2nd London (City of London) General Hospital: Walter Goldie Howarth to be Captain (dated Sept. 26th, 1914).

4th London General Hospital: Captain Ernest Rock Carling is restored to the establishment (dated Sept. 5th, 1914). Captain William Turner is restored to the establishment (dated Sept. 5th, 1914).

1st Northern General Hospital: Sydney James Clegg to be Captain (dated Sept. 30th, 1914).

1st South Midland Mounted Brigade Field Ambulance: Robert Wallace Aitken to be Lieutenant (dated Sept. 30th, 1914).

1st Southern General Hospital: Leonard Gregory Parsons to be Captain (dated Sept. 30th, 1914).

East Lancashire Clearing Hospital: Quartermaster and Honorary Lieutenant Arthur H. Hartshorn, from the 3rd East Lancashire Field Ambulance, to be Quartermaster with the honorary rank of Lieutenant (dated Sept. 30th, 1914).

Add *Attached to units other than Medical Units.*—Surgeon-Lieutenant-Colonel Charles Downing is seconded (dated Sept. 30th, 1914). Surgeon-Captain Henry James Taylor to be Major (dated Sept. 30th, 1914). Captain Edgar Vaughan Phillips, from the 5th Northern General Hospital, to be Captain (dated August 6th, 1914). Surgeon-Captain Jonas W. Anderson, from the 4th Battalion the Royal Welsh Fusiliers, to be Captain (dated Sept. 30th, 1914). Captain Winstan St.A. St. John resigns his commission on account of ill-health (dated Sept. 30th, 1914). Lieutenant Eric D. Gairdner to be Captain (dated August 10th, 1914). Lieutenant Hugh L. Munro to be Captain (dated August 28th, 1914). Lieutenant Ernest W. Reed to be Captain (dated Sept. 1st, 1914). Lieutenant Alexander G. Lovett-Campbell to be Captain (dated Sept. 3rd, 1914). Lieutenant Charles Douglas to be Captain (dated Sept. 8th, 1914). George Bainton Forge to be Lieutenant (dated August 8th, 1914). James York Moore to be Lieutenant (dated Sept. 30th, 1914). Captain Charles J. Martin to be Major (dated Sept. 30th, 1914). Surgeon-Captain John Livingstone, from the Westmorland and Cumberland Yeomanry, to be Captain (dated

Sept. 16th, 1914). Francis Henry Sprague to be Lieutenant (dated Sept. 30th, 1914). Captain John Best McBride to be Major (dated Sept. 26th, 1914). Lieutenant Christopher Francis Murphy to be Captain (dated Sept. 1st, 1914).

COLONIAL MEDICAL SERVICES.

West African Medical Staff.—Dr. J. H. Collier, senior medical officer (Grade III.) Nigeria, has been transferred to the Gold Coast; Mr. N. A. D. Sharp, medical officer, Gold Coast, has been transferred to Nigeria; Dr. A. F. Kennedy has been transferred to Nigeria; and Mr. R. W. Orpen, medical officer, Sierra Leone, has been transferred to the Gambia. Major W. H. G. H. Best, R.A.M.C. (Special Reserve), senior medical officer, Grade I. (Nigeria), has been appointed a Principal Medical Officer in Nigeria. Mr. H. McC. Hänschell has resigned and Mr. J. R. P. Allin has retired with a gratuity. The following have been selected for appointment to the staff: Dr. J. J. Baeza (Gold Coast), Mr. N. S. Deane (Sierra Leone), Dr. J. C. Watt (Sierra Leone), and Dr. J. T. Watt (Nigeria).

Other Colonies and Protectorates.—The following have also been selected for appointment as noted: Colonel J. R. Dodd, R.A.M.C., medical officer in charge of ankylostomiasis work in Trinidad; Mr. C. G. H. Campbell, assistant medical officer for ankylostomiasis work in Trinidad; Dr. A. Kidd, house surgeon of the Victoria Hospital, and bacteriologist, St. Lucia; Dr. R. S. Taylor, temporary medical officer, Uganda; Dr. N. Crichlow, medical officer in the Solomon Islands Protectorate; and Dr. W. M. W. Shepherd, medical officer in Zanzibar.

DEATHS IN THE SERVICES.

Surgeon-General Sir Annesley Charles C. de Renzy, K.C.B., on Sept. 24th, at Ealing, aged 85. He served in the second Burmese War of 1852-3 (medal with clasp), and during the Indian Mutiny he was present at the siege and capture of Lucknow. Later he was appointed first Sanitary Commissioner of the Punjab, and in 1878 Sanitary Commissioner of Assam. He was principal medical officer in the expedition against the Naga hill tribes in 1879, when he was present at the capture of Konoma (mentioned in despatches and awarded a clasp and the Companionship of the Bath). He retired in 1882. He was created a K.C.B. in 1902.

FREE CARRIAGE OF PARCELS FOR THE TROOPS AT THE FRONT. — Messrs. Neale and Wilkinson, Limited, shipping agents, &c., of 32, St. Mary Axe, London, E.C., and 60, Hanover-street, Liverpool, who during the South African war conveyed parcels of clothing, necessaries, and comforts to the soldiers on active service free of charge, have offered to render similar assistance during the present war. The offer has received the approval of the Army Council. Packages of any weight up to 56 lb. will be accepted for free carriage, but in order to comply with War Office regulations no wines, spirits, or matches may be enclosed, nor fresh fruit, vegetables, or any article of a perishable nature likely to cause damage. Full particulars and labels may be obtained from either of the above-mentioned addresses.

UNIVERSITY OF LONDON.—Professor E. A. Minchin, F.R.S., professor of protozoology in the University, will give a course of from 12 to 15 lectures on "Development and Life Cycles in the Protozoa" at the Lister Institute of Preventive Medicine at 5 P.M. on Tuesdays and Fridays during the Second Term (January to March). These lectures, which are free by ticket, will be addressed to Honours B.Sc. students and to medical men, and will be followed by exhibits of preparations as occasion requires.—The following entrance scholarships have been awarded at the London (Royal Free Hospital) School of Medicine for Women: Two St. Dunstan's Medical Exhibitions of the value of £60 a year for three or five years to Miss K. M. Matthews and Miss R. C. Townshend; Isabel Thorne Scholarship of the value of £30 to Miss D. Pantin; Mabel Sharman Crawford Scholarship of the value of £20 a year for four years to Miss L. C. Adam.—On Sept. 1st the Vice-Chancellor (Sir W. P. Herringham) and the Principal (Sir Henry A Miers) addressed a communication to His Excellency the Belgian Minister in the following terms: "On behalf of the University of London we desire to express to the Belgian Government and to the University of Louvain our profound sympathy with them in the cruel loss they have sustained by the destruction of their historic buildings and library, a calamity which has inflicted an irreparable loss not only upon Belgium, but on the whole civilised world."

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING AUGUST, 1914.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 7·5 per 1000 of the population, estimated at 4,516,612 persons in the middle of the year; in the three preceding months the rates were 7·5, 7·6, and 7·8 per 1000 respectively. The lowest rates last month were recorded in Paddington, Hampstead, Stoke Newington, Holborn, and Wandsworth; and the highest rates in the City of London, Bethnal Green, Stepney, Southwark, and Deptford. Scarlet fever was slightly less prevalent than it had been in the preceding month; the greatest proportional prevalence of this disease last month was recorded in Chelsea, the City of London, Stepney, Southwark, Battersea, and Deptford. The Metropolitan Asylums Hospitals contained 3199 scarlet fever patients at the end of last month, against 2859, 3045, and 3113 at the end of the three preceding months; the weekly admissions averaged 414, against 376, 396, and 410 in the three preceding months. The prevalence of diphtheria also showed a decline last month; this disease was proportionally most prevalent in Finsbury, Shoreditch, Bethnal Green, Stepney, Southwark, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1078, 1080, and 1042 at the end of the three preceding months, had further fallen to 1030 at the end of last month; the weekly admissions averaged 128, against 130, 140, and 131 in the three preceding months. Enteric fever was rather more prevalent than it had been in any of the five preceding months; among the several metropolitan boroughs this disease was proportionally most prevalent last month in Fulham, the City of Westminster, St. Marylebone, Holborn, Bethnal Green, and Southwark. There were 39 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 39, 40, and 36 at the end of the three preceding months; the weekly admissions averaged 7, against 6, 8, and 6 in the three preceding months. Erysipelas was proportionally most prevalent in St. Pancras, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Deptford. The 18 cases of puerperal fever notified during the month included 4 in Stepney and 2 each in St. Marylebone and Southwark. The 4 cases of cerebro-spinal meningitis included 2 in Poplar and 1 each in Hackney and in Greenwich; and of the 16 cases of poliomyelitis, 6 belonged to Stepney, 4 to Bethnal Green, and 1 each to the City of Westminster, St. Pancras, Islington, Hackney, Poplar, and Camberwell.

The mortality statistics relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the population of the several boroughs. During the four weeks ending August 29th the deaths of 4378 London residents were registered, equal to an annual rate of 12·6 per 1000; in the three preceding months the rates had been 12·9, 12·6, and 11·3 per 1000 respectively. The death-rates last month ranged from 7·2 in Hampstead, 8·8 in Chelsea and in Lewisham, 9·1 in Stoke Newington, 9·7 in Paddington, and 10·0 in the City of Westminster, to 16·5 in Bethnal Green, 16·9 in Finsbury, 17·7 in Stepney, 18·1 in Poplar, 18·2 in Bermondsey, and 19·8 in Shoreditch. The 4378 deaths from all causes included 707 which were referred to the principal infectious diseases; of these, 149 resulted from measles, 20 from scarlet fever, 29 from diphtheria, 57 from whooping-cough, 10 from enteric fever, and 442 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Paddington, Chelsea, the City of Westminster, Hampstead, Lewisham, and Woolwich, and the highest rates in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. The 149 fatal cases of measles were 58 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Southwark. The 20 deaths from scarlet fever were 2 in excess of the corrected average number, and included 3 in Camberwell, and 2 each in Fulham, St. Marylebone, St. Pancras, Stepney, Southwark, and Bermondsey. The 29 fatal cases of diphtheria slightly exceeded the corrected average number, and included 3 in Islington, 3 in Bethnal Green, 3 in Stepney, and 2 each in the City of Westminster, Poplar, Southwark,

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

and Lambeth. The 57 deaths from whooping-cough were 4 above the corrected average; the highest death-rates from this disease were recorded in the City of Westminster, Finsbury, Shoreditch, and Southwark. The 10 fatal cases of enteric fever were also slightly above the corrected average number, and included 2 in Hackney. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was 35·9 per cent. above the average.

THE REFUGEES AT THE ALEXANDRA PALACE.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

THE small pile of smoking ruins representing what remained of the Belgian peasant's home must contrast curiously to his eyes with the lofty structure of the Alexandra Palace. Some of the poor guests we are now sheltering in the Palace had never left their native settlements; they had not even seen any of the larger towns of Belgium. Then suddenly, before they had quite grasped the fact that war had been declared or what war meant, their little village was invaded. Under the pretext that some civilian had fired at the enemy, murder, arson, and rapine followed. Those who could escape hid in the woods, the quarries, and sometimes even in sewers. In time, after in some cases three or four weeks of wandering, sleeping under hayricks and stealing forward from various places of concealment, a family, fortunate indeed if it still remained a complete family, terrified, bedraggled, weatherworn, and utterly exhausted, would reach Antwerp. But Antwerp is a beleaguered city, and must think of the situation from that point of view. So the Belgian peasants are given some little temporary aid, are medically examined to see that they are free from infectious disease, put on board an English ship, land in due course at Tilbury, and suddenly find themselves in the huge palace which used to be the holiday resort of North London. Such an experience must have seemed like a fantastic dream to many; it is, in fact, exactly such an episode as constantly occurs to dreamers in the "Arabian Nights' Entertainments."

Work at Express Pace.

Notwithstanding the spaciousness of the Palace, with its lofty walls and great domed roofs, the magnificent views over the great metropolis, the stately trees, the smooth grass lawns, the smiling flowers—notwithstanding all this, the grim realities of the heart-rending drama enacted on these former pleasure grounds cannot be entirely concealed. The very hurry with which everything had to be done was distressfully dramatic. It was on Sept. 4th that the first notice was given to the officials at the Local Government Board that the reception of refugees would be committed to them. Efforts were at once made to secure the Crystal Palace, and though this negotiation was not successful 200 refugees were lodged there while the matter was being discussed. On Sept. 5th the old Poland-street workhouse was secured. This building was about to be destroyed. The water and the gas fittings had already been removed, and had to be replaced with all speed. Luckily, the drains were still in good order. On Sept. 6th the Local Government Board secured the former Edmonton and Hackney workhouses. By that time 447 refugees had already come over. On the following day intimation was given that thousands, not hundreds, were expected—20,000 from Antwerp and 30,000 from Ghent. The position was therefore serious, particularly as no arrangement could be made with the Crystal Palace. On Sept. 8th the Alexandra Palace was secured, the gates were closed, the Government took over the building and the grounds, and at once asked the Metropolitan Asylums Board to convert it into a refuge. By Sunday, the 13th, they had already extemporised 1000 beds, and, as related in my report last week, by Monday, the 14th, no less than 925 refugees had arrived.

Fortunately, recent alterations in methods of poor relief have brought about the abandonment of many old workhouses, and the number of cells required for casuals has been reduced from 1100 to 200. Thus the celebrated St. Giles workhouse in Endell-street was vacant, and here also 1000 beds were promptly prepared. The workhouse which the old Strand Union built at Edmonton, and which was going to be converted into an asylum for imbeciles, has likewise been temporarily handed over to the Local Government Board and can accommodate another 1000 refugees. The Endell-street workhouse was to have been used as a refuge for dependents on German suspects; but as they were not numerous they were sent to the workhouse in St. Mary's-place, Kensington. The Kensington, St. Pancras, Hackney, and Westminster infirmaries provided temporary accommodation for the sick and for lying-in cases.

Freedom from Infectious Disease.

The whole system of isolation of the Asylums Board is available for infectious cases; but the refugees so far have been fortunately free from such complaints. Here and there a child with whooping-cough has been detected, and one or two children had symptoms of scarlet fever. Only at Folkestone have two refugees been detained because they were suffering from small-pox. Thus it will be seen that there is a remarkable absence of zymotic disease, but this is no reason for relaxing the careful watch that is kept upon the new arrivals. Indeed, measures are taken to extend this watchfulness indefinitely. It is not proposed that the refugees should remain in the asylums, and I believe that they can be immediately allotted to private families willing to offer them hospitality. Wherever they may go the mayor and sanitary authorities of the locality must be informed, and the latter must make inquiries from time to time as to the health of the nation's guests. On the other hand, a strong feeling has arisen from experience that it would be wiser and better in every way to retain the refugees for a few days before they are sent off to live in private families.

First Care of the Refugees.

It must be borne in mind that many of the refugees are ignorant as well as poor peasants, and though very clean many of them have never seen a bathroom or a water-closet. At the Alexandra Palace one of the first steps taken was to teach the refugees how to use the water-closets. It was necessary to prevent them from standing on the seats and from throwing all manner of things into the pan that might block the drains. Such teaching was the more urgent, as the need of closets being much greater for residents than for visitors, the number provided at the Alexandra Palace, which was not built for dwelling purposes, was at first insufficient. Therefore supplementary latrines were set up in the grounds. Immediately on arrival the refugees need not only good baths but some of them are very miserable for want of clothes. Fortunately at the Palace there is a large compartment with piles of clothes, gifts sent for the use of the refugees. It takes time, however, to distribute these to the best advantage.

The Alexandra Palace is being used as a clearing-house for the refugees, but from the above it will be seen that before putting them into a strange English home it would be preferable to keep them for a few days under observation at the refuge. Thus they may learn a little about English ways, get partially accustomed to the change of scene, get better fitted with clothes, and perhaps even pick up two or three words of English. If there is any latent sickness it may thus be found out. At the Alexandra Palace the "Bijou theatre" has been converted into an excellent hospital with snug little cots for the children. The matron, Miss Cockerell, was matron of the Marylebone Infirmary. Her services, lent by the Marylebone guardians, have proved of great value to the Belgian refugees.

Sleeping Accommodation.

The train on arrival enters the Palace grounds, but it is necessary to ascend a broad flight of steps before reaching the inside of the building. This is fortunate in a way, for by placing barriers made with rows of chairs the crowd can be divided up and the business of allotting beds to each rendered less difficult. Of course, there are no bedrooms at the Alexandra Palace, and when the structure was first taken over it was not possible to obtain any bedsteads whatsoever. It seemed as if every available bedstead had been sold and that it would be necessary to wait till more could be manufactured. At first, therefore, all that could be done was to place mattresses on the floor. Nor was it possible to provide more bedding than a pillow and some rugs. In a few days pillow cases were made and by Sept. 21st the Metropolitan Asylums Board was able to obtain 1000 bedsteads, which were to be delivered promptly; and further deliveries of 1000 bedsteads per week are promised. None had arrived when I visited the Palace, and it was a queer sight to see hundreds of beds on the floor with a chair as a sentinel separating mattress from mattress. In one gallery, on the first floor, with a magnificent south view and a broad balcony that would be admirably suited for out-of-door medical treatment, there were 360 beds on the floor. The window space takes up a good third of the wall space, and there are windows facing which give on to the corridor, and thus a through draught can be established. The height of the galleries also helps to secure an ample air-supply. The skating rink, which is likewise very lofty, has 400 beds, and there is a ventilation air-exhaust all round the ceiling. A part of the great central hall is screened off and we have some hundreds of beds there. The orchestra, at the foot of the grand organ, having numerous immovable and numbered seats, has ingeniously been converted into a vast parcel or cloak depôt. Each refugee has one of the numbered seats allotted to him, and there places his bundle, packet, box, or whatever he may have with him. Where the musicians usually sit there is now a vast collection of the most inharmonious luggage.

Good Food, Good Air, and Rest.

Then we have the question of food. The kitchens at the Alexandra Palace had been filled up with lumber and the kitcheners removed, for the premises were not in use. To clear all this away and to bring in cooking apparatus and crockery it was necessary to work night and day. Fortunately the services of a very able Belgian chef were secured, and electric power machinery for cutting bread, preparing vegetables, and grinding coffee was quickly introduced. All laundry work is sent out to the Asylums Board laundries. Thus, even for the first arrivals hot meals were ready. On the day of my visit they had leek soup, so succulent and delicately flavoured that many of the refugees demanded three helpings. In how many English homes are they likely to obtain skilfully prepared leek soup?

The attendants grew eloquent on the improvement wrought in the appearance of these poor people after they had spent a day or two at the Palace. Of course, it is in the children that the signs of recuperation show themselves first, as I can testify from my recollection of the appearance of the landing parties. There is much to divert the children in the Palace. Some trace of the old shows still remains, notably a large cage with beautiful parrots. Various strangely decorated, even if empty, stalls are stared at with wonder. Then there are statues, a few pictures, and many fine semi-tropical plants, some swings in which the children delight, and the vast grounds with flower beds, trees, and soft green grass. The air also is pure and bracing. To stay at the Alexandra Palace is the most suitable tonic that could possibly have been prescribed so as to revive and restore these suffering victims of a most cruel war. Many of our luckless guests have suffered too much and have lost too much to be immediately influenced in a great degree by shelter and kindness, but the improvement, physical and mental, is there and gradually shows itself.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.—After an examination on Sept. 21st and 22nd the following awards have been made. Entrance scholarship in arts (value £100), J. T. Long (Coopers' Company's School) and D. Spurway (Bridgnorth Grammar School), equal. Jeaffreson exhibition (value £50), A. B. Bernard (Dulwich College).

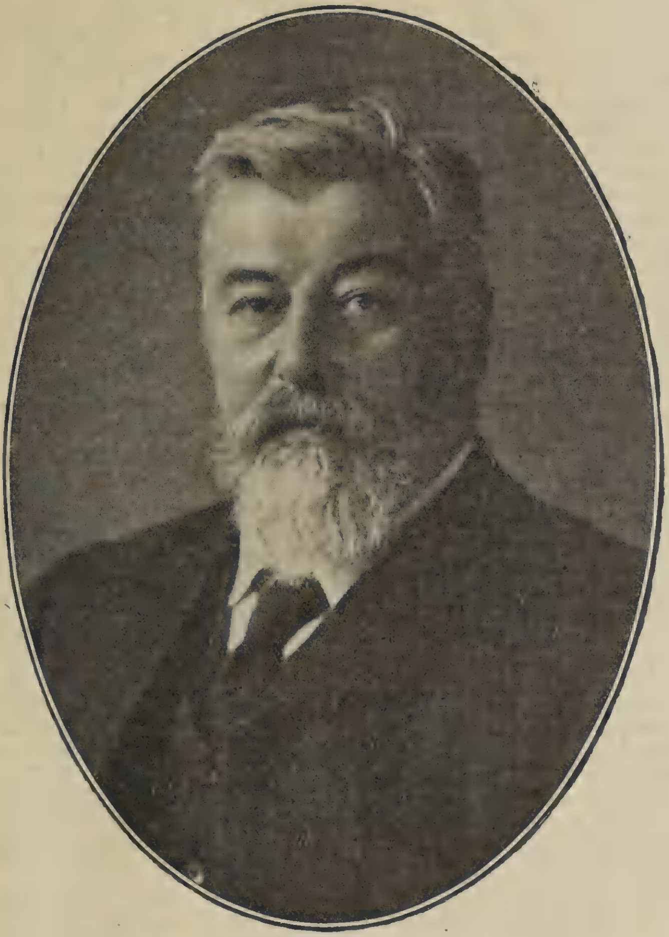
LONDON PANEL COMMITTEE.—As London panel practitioners are receiving this week the £90,000 accumulated in 1913 in respect of insured persons who had not chosen a doctor, the Panel Committee on Sept. 29th decided, as a thankoffering and a suitable gift from members of the medical profession at the present juncture, to invite the 1500 doctors concerned to subscribe towards a present of a motor ambulance for the British Red Cross Society. It was decided not to accept membership of the proposed Federation of Local Medical and Panel Committees as at present constituted. It was objected that as the metropolis has its own special problems the Panel Committee could not bind itself to take no important action without first consulting the Federation, on whose executive it would only have two members out of 15. Discussion took place on a list, promulgated by the Insurance Committee, of proprietary and other drugs and appliances which, it was suggested, should be definitely excluded from insurance prescribing. It was felt undesirable that the precedent should be established of permitting a lay body to dictate in the matter of prescribing, and that the best method of checking any excessive prescribing would be to require individual practitioners to justify to the Panel Committee prescriptions to which objection was taken. Resolutions embodying this view were passed.

Obituary.

WALTER HOLBROOK GASKELL, M.D. CAMB., F.R.S., HON. LL.D. EDIN. AND McGILL,

FELLOW OF TRINITY HALL AND UNIVERSITY LECTURER IN PHYSIOLOGY, CAMBRIDGE.

IT is safe to say that to no physiologist does medicine owe a debt greater than that which it owes to Walter Holbrook Gaskell, for, in the course of his work on the sympathetic nervous system, he laid for all time the foundations of the pathology of the heart. Broadly speaking, Gaskell may be said to have accomplished two things—he determined the functional relations of nerve cell and muscle fibre, especially of cardiac and plain muscle fibre; and he gave us a complete and consistent theory of the general functional and anatomical relations of the nerve fibres and nerve cells of the sympathetic system. When in 1874 he went, at Michael Foster's suggestion, to Leipsic to Ludwig's laboratory, it was with the intention of working at problems connected with the sympathetic system, and his first work, which appeared in Ludwig's *Arbeiten*, dealt with the regulation of the blood flow through skeletal muscle—that is to say, with the way in which the varying degree of contraction of the muscular coats of the arteries is brought about. From this he passed to the general question of the functional relation of nerve cell, nerve fibre, and muscle fibre, especially with reference to the cause of the rhythm of the heart, and the nature of action of the cardiac and vaso-motor nerves. The completion of the work on the heart in 1881 was followed by a return to the general problem of the minute anatomy and function of the sympathetic system and its relation to the central nervous system; and the results were published in the *Journal of Physiology* in 1886 in a paper on the Structure, Distribution, and Function of the Nerves which Innervate the Visceral and Vascular Systems.



WALTER HOLBROOK GASKELL.

(Reproduction of photograph by Messrs. Elliot and Fry.)

When Gaskell began to work the nerve cell was looked upon as the sole cause of the contraction and tone of muscle. Therefore, since the heart can continue to beat when its connexions with the central nervous system are severed, its automatic properties were supposed to lie in the nerve cells of the cardiac ganglia. Similarly, when it was discovered that the loss of tone in the arteries which follows on severance of the nerves going to them is only temporary, the recovery was ascribed to the action of peripheral ganglion cells, which by sending out "tonic" nervous impulses restored and maintained arterial contraction.

At no time in his career did Gaskell fall under the spell of this doctrine. The very earliest experiments carried out in Ludwig's laboratory in 1874 convinced him that at the least it did not contain the whole truth. His earliest papers were written to prove that the muscle cell is not merely the passive instrument of the nerve cell, but is the seat of independent activity and responds directly to changes in the lymph or blood. From this followed the important conclusion that in the regulation of the blood flow through an organ the direct influence of chemical substances, produced locally by the cells of the organ, upon the muscular coats of the arteries must play an important part. The possession of independent rhythmic activity by plain and cardiac muscle was directly proved when strips of such muscle absolutely devoid of nerve cells were found to be capable of beating regularly. We now know that ordinary skeletal muscle—so typically passive during life—has the property of automatic action so little obscured as to be restored by a slight change in the salt content of the fluid bathing it. But in the "seventies" the admission of automatic powers outside the nerve cell was as novel as the admission that animal protoplasm possesses synthetic powers which Ludwig compelled a still earlier generation of physiologists to make.

The course of the cardiac systole was at first sight less easily understood as a purely muscular event. How in the absence of nervous coördination could the orderly sequence of contraction of the chambers be brought about? Gaskell solved the difficulty in the simplest way. He showed that a beating strip of muscle free from nerve cells is divided into two portions beating in sequence when the wave of contraction is partially blocked at one part by cold or pressure. This led him to his final conception of the systole as a wave of contraction which starts in the roots of the great veins and sweeps without a break over the cardiac muscle to the aorta. At the junction of the auricles and ventricles the wave is delayed by the presence there of relatively slowly conducting tissue so as to provide the necessary pause between the auricular and ventricular systoles.

The work on the nerves of the heart must rank as of equal importance with the proof of the automaticity of the muscular fibre. This work may be said to have provided a clear account of the structure and opposed functions of inhibitory and accelerator fibres previously much confused, and to have settled their place as specialised homologues of the vaso-constrictor and vaso-dilator fibres of the arteries. Probably the most fundamental observation made lies in the discovery of the opposite electrical effects produced in the muscle by stimulation of the two sets of nerve fibres. Stimulation of the accelerator fibres provokes an electrical change similar to that typical of muscular contraction; stimulation of inhibitory fibres produces a change the opposite to this. These electrical changes are independent of contraction since they can be observed in the completely quiescent heart. The recent striking progress towards a final theory of the processes of excitation and contraction has made clear the profound significance of this observation. It has not yet taken its place in the interpretation of the electrocardiogram. In 1881 Gaskell gathered the fruits of his work on the heart into the Croonian lectures of that year. No one who hopes seriously to advance the pathology of the heart can afford to neglect the study of this work; it cannot be taken at second hand.

To appreciate justly Gaskell's contributions to biological science it must be realised that his work on the heart, complete and far-reaching as it is, is only a fragment of his larger work on the sympathetic system. Any summary which could be attempted here must be so inadequate as to be ridiculous. All that can be done is to point out that whereas before his time the sympathetic system was regarded as a second system existing side by side and comparable with the central nervous system, from which it received the white rami communicantes, and to which it sent the grey rami, it is, owing to him, now known to be merely the highly specialised outflow of nerve fibres from the central nervous system to the visceral and vascular systems. The combined penetration and breadth of view which characterise the great paper of 1886, already alluded to, mark it one of the most remarkable achievements in the literature of science.

The attempt which Gaskell made in the years following 1881 to express the structures of the brain in terms of a typical segment of the spinal cord led him to formulate a remarkable theory of the origin of the central nervous system of vertebrates, according to which the central canal is the lumen of a primitive gut. This view has been much contested, and it cannot be said to have won the support of morphologists; but whatever the final verdict may be, the admirable work done in connexion with it upon the nervous system and allied organs of *Limulus* and the lamprey is of lasting value. Mention must be made of one special service rendered to medicine. Gaskell, in conjunction with Dr. L. E. Shore, proved by a series of bold experiments that the fall of blood pressure which follows administration of chloroform is due to the action of the drug upon the heart, and not, as had been maintained, upon the vaso-motor centre. The investigation of the action of this drug was undertaken at the request of the Hyderabad Commission.

Dr. Gaskell came of the well-known Unitarian family of that name in the North of England. He was born at Naples on Nov. 1st, 1847, the son of Mr. John Dakin Gaskell, barrister, and Anne, his wife. He received his early education at Sir Roger Cholmeley's School, Highgate, and entered Trinity College, Cambridge, in 1865. There he studied mathematics and his name appears amongst the wranglers of 1869. Michael Foster, as prælector in physiology at Trinity College, had then just begun his great work for the biological school at Cambridge, and Gaskell was one of the small group of young men caught and trained by him. After taking his degree in 1869 he proceeded to University College to study medicine, and took his M.D. degree in 1878. He received the Marshall Hall prize in 1888, a Royal Society medal in 1889, and the Baily medal in 1895. He served with distinction upon the Moseley Commission and the Vivisection Commission.

Dr. Gaskell was a brilliant lecturer, perhaps the most inspiring that the Cambridge student ever had the good fortune to listen to, not excepting even Foster himself. In the quiet simplicity of his character personal pride had no place. His students found in him a personal friend, and those who know the Cambridge school will know well how strong was the affection they one and all had for him.

OPEN-AIR HOSPITALS IN WAR TIME.

To the Editor of THE LANCET.

SIR,—Professor Robert Saundby in his article on open-air hospitals in war time in THE LANCET of Sept. 19th makes no reference to the open-air treatment of acute specific fevers. This has been practised with much benefit to the patients, and without untoward results in any case, at the city isolation hospitals of Nottingham for nearly 20 years. Large glass-covered verandahs, 45 feet long by 20 feet wide, are attached to the permanent blocks, and upon these our patients are placed and nursed at all stages of the disease and practically in all weathers. These hospitals have been visited by numerous medical officers of health and other representatives of local authorities in recent years, and the practice of treating cases of acute specific fevers of all kinds in the open air is now slowly growing in public favour in various parts of the country.

The late Dr. H. Franklin Parsons, first assistant medical officer to the Local Government Board, paid a special visit to these hospitals in 1910, and gave a lengthy account of them and of our methods of treatment in his report to the Board in 1912. He stated in this report that he saw nothing in the course of a lengthy inspection and inquiry to cast any doubt upon the accuracy of our statements in favour of the system. Also, in his posthumous work on isolation hospitals issued in 1914 from the Cambridge University Press, he again expresses himself to the same effect, and states that the system is worthy of an extended trial.

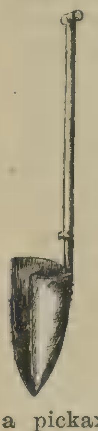
It is, in my opinion, of special importance that the advantages of open-air treatment for acute specific diseases (including small-pox, enteric fever, and dysentery) should be recognised at the present time, for if the present war continues we are likely to have a great deal of such disease to treat, and a full recognition at once of the freedom from risk and active advantage of this line of treatment for practically all classes of cases may be of the highest utility alike to the sick and the healthy. I am, Sir, yours faithfully,

Nottingham, Sept. 26th, 1914. PHILIP BOOBBYER.

MILITARY SANITATION.

To the Editor of THE LANCET.

SIR,—There is ample evidence in the crusade for antityphoid inoculation, and care as to water and soil purity in camps, that possibilities of epidemics of typhoid following embodiment of Territorials and the new army are being guarded against. Route marching, bivouacs, and manœuvres by large numbers of men, however, imply chances of soil and indirect water contamination which camp arrangements will not meet in the case of troops, whilst they especially render the civil population in areas under military occupation liable to infection. Under such conditions, the method of emergent conservancy laid down in Deut. xxiii. 12, 13, should be of utility. In peace time, the addition of a spade per company of the pattern shown in the annexed diagram should not be objectionable as an extra weight. The shaft can be made folding or removable. If the garden trowel-shaped portion of the spade be of steel with an edge, and on the shaft be arranged a projection at right angles (to enable pressure to be applied by the foot in thrusting) it should be possible, in readily penetrable soil, to make quickly numerous holes for defæcation purposes of 6 inches in diameter and 8 inches to 9 inches deep, by making two semi-circular cuts for each. If the removed soil be placed at the edge of the hole, a movement of the foot fills it in quickly after defæcation by squatting. The employment of a pickaxe or crowbar to accomplish the same work requires much time, and produces irregular results. In time of war, the use of the "entrenching tool" for this purpose might often be advantageous. If the user faces the little heaps of removed soil, even the objection to urine-borne microbes is largely met. I have used this cleanly, inodorous, and rapid method freely in the great gatherings which attend fairs and festivals in India. I am, Sir, yours faithfully,



W. G. KING,
Colonel I.M.S. (retired).

Hatch End, Middlesex, Sept. 21st, 1914.

THE WOMEN'S NATIONAL SERVICE LEAGUE HOSPITAL.

To the Editor of THE LANCET.

SIR,—On Sunday afternoon last the Women's National Service League sent a fully equipped hospital to Antwerp to help the Belgian Red Cross. Mrs. St. Clair Stobart, whose recent experience as a prisoner in the hands of the Germans has been the subject of much press comment, was in charge of the unit, which consisted of six women doctors and surgeons (Dr. Florence Stoney, Dr. H. B. Hanson, Dr. Rose Turner, Dr. Emily Morris, Dr. Joan Watts, and Dr. Mabel Ramsay), 12 fully trained nurses, cooks, orderlies, and electricians in charge of the X ray apparatus.

Sir Cecil Hertslet, British Minister at Antwerp, had sent pressing messages to Mrs. Stobart to start at once, as the wounded were daily coming in and beds and all hospital equipment were badly needed. The St. John Ambulance kindly gave every possible assistance and countenance to the unit. The hospital equipment for 130 beds was perfect in every way. Lady Cowdray had generously presented the necessary X ray apparatus. The Hampstead Garden Suburb subscribed £200 towards the equipment. Mrs. Warwick Hunt, besides fully equipping 25 beds, has made a handsome present of 166 pairs of sheets. Other generous donors are Mrs. Fagan, Mrs. Frederick Guest, and Miss Cunliffe. Sir Alfred Mond and Miss Donisthorpe are both making weekly donations towards the maintenance of the hospital, but further funds are urgently needed if we are to free the hardly pressed Belgian Red Cross of all monetary responsibility. Donations, large or small, all of which will be gratefully acknowledged, should be sent to Lady Muir-Mackenzie, Women's National Service League, 39, St. James's-street, London, S.W.

I am, Sir, yours faithfully,

Sept. 25th, 1914. THÉRÈSE MUIR-MACKENZIE.

BERMONDSEY GUARDIANS AND OUTDOOR MEDICAL RELIEF.

To the Editor of THE LANCET.

SIR,—I notice in THE LANCET of Sept. 26th an advertisement of the Bermondsey guardians for a whole-time medical officer to take the place of the old part-time district medical officers in that union, under a recent scheme sanctioned provisionally by the Local Government Board for five years. With your permission, I should like to draw the attention of intending candidates to certain drawbacks that do not appear on the face of the advertisement. This scheme has been strongly condemned (1) by the local profession, as represented by the Camberwell Division of the British Medical Association; and (2) by the Poor-law Medical Service of England and Wales, as represented by our association. Although the salary offered may appear generous as compared with some Poor-law salaries, there are conditions attached that very considerably diminish its value. Deductions proportionate to the salary have to be made under the Poor-law Officers Superannuation Act. As there is no security of tenure for the medical officer these deductions may never mature in the pension for which they are compulsorily levied. If returned on the officer's dismissal, or the determination of his office, their insurance value at all events will be entirely lost; and in the case of a young married man such a contingency ought not to be overlooked. By the Poor-law Orders medical officers of the kind advertised for are not recognised. The Poor-law Orders know only district medical officers and workhouse medical officers, medical superintendents of infirmaries being included in the latter category. Both of these classes are given security of tenure, and are not entirely at the mercy of the guardians.

At the inception of this scheme the Poor-law Medical Officers' Association approached the Local Government Board and strongly urged the equity of putting these new medical officers, who were to take the place of the old district medical officers, under the protection of the Poor-law Orders, but without success. It only remains, therefore, that all medical practitioners who accept such posts as these should at least understand fully the responsibilities they are taking upon themselves.

I am, Sir, yours faithfully,
MAJOR GREENWOOD,
Honorary Secretary, Poor-law Medical Officers' Association of England and Wales.
London, E.C., Sept. 28th, 1914.

To the Editor of THE LANCET.

SIR,—In THE LANCET of last week appears an advertisement from the parish of Bermondsey for a medical officer whose duties shall consist of "attending to the sick poor of the parish in the institutions or in their own homes under the direction of the medical superintendent of the infirmary." Might I suggest to any intending applicants to make a searching inquiry as to whether the conditions of this advertisement are applicable to the appointment of district medical officer under the Poor-law—i.e., whether the officer appointed is in reality an officer of the Poor-law at all with all the advantages of permanency of office and a prospective pension, or whether in reality he should not have been advertised for as an assistant to the medical superintendent of the infirmary, liable at the caprice of that officer or even of some member of the board of guardians to have his appointment determined at short notice without compensation of any kind whatever. I see the advertisement asks for an experienced man. Can any experienced responsible man be found capable of being tempted even by the bait of a fairly adequate salary to accept such conditions? I also see preference will be given to a married man. Will any married man be found to risk his whole future and that of his wife and family on such a doubtful speculation?

Reading the account of the meeting of the Poor-law Medical Officers' Association in the issue of the *Poor-law Officers' Journal* for Sept. 18th, p. 1229, it is there stated that the Local Government Board only gave its sanction to this appointment on a "five years' trial." This is not stated in the advertisement. Was the omission accidental? Anyhow, to intending applicants I would say, Beware! I am, Sir, yours faithfully,
Sept. 29th, 1914. D. M. O.

CHOLERA BELTS.

To the Editor of THE LANCET.

SIR,—As considerable time is at present being spent in making so-called "cholera belts" for the troops, it would be interesting to obtain the opinion of your readers as to the usefulness of these articles. In eastern climates these abdominal belts are, I believe, considered to be some protection against certain intestinal disorders, and their designation, I presume, suggests that they are even of some service in warding off cholera.

Whatever may be their usefulness under certain conditions, I feel certain that their disadvantages outweigh their advantages for troops on active service. Experience in South Africa showed that unless frequently changed, which is an impossibility for troops at the front, they soon teem with vermin. They become soaked with perspiration and rucked up during exertion and form an uncomfortable damp girdle which has a tendency to cause local chill during subsequent rest. There is, moreover, a definite danger in suddenly dispensing with such an article after becoming accustomed to its use, but the troops must often have to choose between such a course and continuing to suffer considerable local irritation and discomfort.

I am, Sir, yours faithfully,
J. COOTE HIBBERT.
Public Health Office, Blackburn, Sept. 25th, 1914.

HELICON.

To the Editor of THE LANCET.

SIR,—I am pleased to see the advertisement of "Helicon" in your issue of last week. I find that helicon and aspirin are identically the same.

Now is the time. Prescribe helicon and put money into English pockets and not aspirin and money in German pockets. This is to be a war of endurance, and the length of the purse will settle it. I am, Sir, yours faithfully,
Hove, Sept. 28th, 1914. EDWARD TREVES, M.R.C.S.Eng.

⁂ The question is not perfectly simple. Application was made this week to the Comptroller-General of Patents with regard to a company of almost entirely German personnel formed to manufacture an article in Germany, where the manufacture had been transferred to England, all labour and material being now entirely English. The Comptroller said that it was not the Government policy to close all German concerns when they were carried on for the benefit of British labour. We have received from Mr. A. Newton, the present proprietor of Pneumosan, a statement that his is a British product, only British labour being used, and that the business will be carried on henceforth under the style of The Pneumosan Company.—ED. L.

GIFT TO THE SEAMEN'S HOSPITAL SOCIETY.—Mrs. E. Spencer Stidolph has presented to the Seamen's Hospital Society the freehold property of Highbridge House, Greenwich. The building was originally a part of the Crown and Sceptre Inn, a resort of Charles Dickens.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—At examinations held recently the following scholarships and exhibition were awarded:—Open scholarships in natural sciences: J. O'F. Fletcher, St. Mary's College, Trinidad; W. F. Francis, Berkhamsted; and H. E. Suter, Epsom College. University scholarships: J. W. G. Phillips, St. Mary's Hospital Medical School; and T. S. Evans, University College, Cardiff. University exhibition: R. A. Woodhouse, Downing College, Cambridge. Epsom college scholarship (by nomination): R. L. Walker.

COUNTY TYRONE TUBERCULOSIS COMMITTEE.—The Irish Local Government Board have advised the County Tyrone Tuberculosis Committee not to provide a large residence for their medical officer, but the committee have decided to recommend the county council to borrow £1350 to do so, the conditions being that the doctor is to pay £45 annually as rent. It was also decided to request the joint committee of Castlederg, Cookstown, and Dungannon to fall in with a suggestion that the fever cases in Cookstown Hospital should be transferred to Dungannon Fever Hospital, and that the former building should be utilised for the isolation of advanced tuberculous cases.

THE PREMIER AT PEAMOUNT SANATORIUM.—Last Saturday morning Mr. Asquith occupied the few hours at his disposal before his return to England from Dublin by a visit to Peamount, the sanatorium maintained in county Dublin by the Women's National Health Association. The Prime Minister motored to Peamount in company with their Excellencies the Lord Lieutenant and the Countess of Aberdeen. The party inspected the sanatorium, and Mr. Asquith declared a new pavilion for children open. This is the first special accommodation for children in any sanatorium in Ireland. It was reported that two male patients who had been in the reserves had so far recovered as to be able to join their regiments for active service.

THE WAR.

THE ORGANISATION OF MEDICAL SERVICE IN THE FIELD.

(Continued from p. 824.)

THE third zone of field medical administration is the *distributing zone.* Included in the line of communications are stationary hospitals, general hospitals, base medical store depôts, convalescent depôts, and ambulance trains. The stationary hospitals, two for each division, are organised for 200 beds each, but are capable of expansion. They should preferably be established in permanent buildings, if suitable ones are obtainable. General hospitals, two for each division, are established of 520 beds each, capable of expansion, and are accommodated in buildings if possible. Base depôts of medical stores are formed in the proportion of one for every two divisions. The use of convalescent depôts in connexion with general hospitals is in order to relieve pressure, so that accommodation may be always available in these latter for serious cases arriving from the front. Transport of sick and wounded from the seat of operations by railway is the best means of speedy evacuation, and is always adopted where feasible. Ambulance trains consist of special coaches built for the purpose, to convey stretcher cases, and are provided with dispensary, kitchen, pack store, &c., with corridor communication. Improvised ambulance vehicles equipped with special apparatus for conveying lying-down cases are also used. The Zavodovski method for slinging eight ordinary pattern stretchers in the usual railway van is easily practicable. Empty supply trains returning to the base are available for transport of ordinary (not severe) cases of sickness or injury. When the line of communications is long and halts or detrainings of sick or wounded are necessary, rest stations, with the means of providing medical aid, should be established.

The last stage in the transport of sick and wounded from an overseas expedition is that by means of hospital ships, one for each division of an army in the field, equipped for 220 beds, and forming a link between the base of active operations and the large military hospitals at home, where the final treatment of serious surgical and medical cases is carried out. When further active treatment is no longer required the convalescent patients are accommodated in depôts until again fit for duty, or until finally invalided. In the present campaign numerous civil hospitals have been utilised in various parts of the country, to supplement the accommodation of the military hospitals at Netley, Woolwich, in London, and elsewhere.

Attention was directed last week to the means for providing aid in the first place to the wounded; the army has its *raison d'être* in the necessity for fighting, and fighting implies liability to injury, which may be slight, or severe, or mortal. If slight, the patient returns to duty after a few days, without needing to be sent away from his unit. If mortal, the last offices are brief, the cause and date of death are recorded, and the regimental number is crossed out. If the injury is severe and the force is advancing, the man must necessarily be left at the spot or sent down the line of communications; and even if the injury is comparatively slight, if the force is advancing, the injured man must be sent back; he cannot stay where he is, and he cannot be allowed to advance unless he is fit to fight. It is frequently difficult to decide what to do with such cases. Any interference with the ability to march or shoot of course necessitates relegating the patient to hospital. In other cases it is a question between burdening the hospital accommodation and transport arrangements with trivial cases of sickness or injury, and encumbering the fighting line with an individual not absolutely fit. The idiosyncrasy of the man is the determining factor in many cases, and the regimental doctor must decide. In case of doubt as to absolute fitness, it has to be remembered that it is a less evil that the line of communications should be burdened with slight cases of illness than that the vigour of attack or stubbornness of defence should be impaired by the presence of men not physically fit.

But it is not only the wounded that fall out of the fighting line and need the care of the medical officer. Sickness may be a greater danger to the army than the bullets of the enemy. The nature of the climate and of the country, the length of the campaign, and the physical characteristics of the troops (e.g., whether they are seasoned soldiers or immature recruits) have an important bearing on the possibility of maintaining an efficient force in the field. Dysentery and enteric fever are the chief diseases to be feared, and, in warm climates, cholera. Protective inoculation is now available against cholera and enteric fever, and is being carried out as regards the latter as far as circumstances admit, though, from the shortness of the time available, it cannot have been possible to protect more than a small proportion of the troops that have proceeded on service. The sanitary organisation of the Army, laid down in general terms by the regulations and administered by the principal medical officer of the force according to the circumstances of the country and climate, is carried out in detail by the individual field units under the immediate supervision of the medical officer in charge. Combatant officers are now fully alive to the importance of taking all necessary measures for maintaining the health of their men; and although it cannot be expected that, with such large numbers exposed to the hardships and unavoidably insanitary conditions of field service, there will be an entire absence of epidemic disease, we may hope that there will be no widespread epidemic. It is certain that never before has an army left these shores so well equipped for service or under the care of a more competent, skilful, and devoted body of medical officers. Nor at any time has the importance of preserving the health of the troops, by taking the greatest care as to their feeding, clothing, and comfort, and so maintaining their efficiency, been so entirely recognised as by the military authorities in making the arrangements for the present Expeditionary Force.

THE TREATMENT OF THE WOUNDED IN THIS COUNTRY.

IN this country we are concerned with those wounded who by the operations in the evacuating zone land on our shores from the base hospitals abroad, having reached these from the clearing hospitals and stationary hospitals on the lines of communication (see THE LANCET, Sept. 26th, p. 824). Our wounded arrive at Southampton, and are distributed according to available beds from lists supplied twice weekly to the embarkation officer. The accommodation for the wounded is triple. There are, first, the Permanent Military Hospitals; there are, secondly, the base hospitals belonging to the Territorial force which come into effect on mobilisation; and there are, thirdly, the big charitable institutions of the country, the civil hospitals, whose authorities have placed a certain number of beds at the disposal of the War Office. These last institutions have in some cases become definitely attached to the Territorial Base Hospitals, as well as supplying them with their *à la suite* staffs, the beds in the civil hospitals which have been ceded to the War Office constituting a section of the respective Territorial hospitals. The Territorial Base Hospitals are technically known as "general" Territorial hospitals, a title which it must be remembered is correct, though confusing.

The Permanent Military Hospitals are in association with the various commands. Thus the Aldershot Command is served by the Cambridge Hospital and the Connaught Hospital, each having about 500 beds, and there is also a small isolation hospital. The Eastern Command has four hospitals, one at Colchester, one at Chatham, one at Warley, and one at Woolwich. Of these the Royal Herbert Hospital at Woolwich contains over 600 beds and Colchester over 200. In the Southern Command there are five hospitals, among them being the principal military hospital in the country, Netley, which will hold 1200 patients at all times, and which can easily take 800 more in temporary buildings on the grounds. There are also the Devonport hospital, 250 beds, that at Tidworth, 150, and that at Portsmouth (Cosham), 200. At Netley a Red Cross hospital of 500 beds is now under construction. We need not enumerate the other military hospitals whose locality is indicated in the Army List by the addresses of the various divisions in each command. They are staffed by the Army Medical Service. The aggregate number of beds in these hospitals in England and Wales is nearly 6000; there are 1000 beds in Ireland, and about a quarter of that number in Scotland. These hospitals form the first accommodation for the wounded in this country during war, while in peace time they have the responsibility of caring for the health of the army.

The Territorial Base Hospitals form the second accommodation. They only come into existence upon mobilisation. They each possess a peace establishment of three officers, colonel, major, and quartermaster, and 43 others, and an *à la suite* staff comprised, as a rule, of the medical staff of a great hospital or infirmary in the neighbourhood, in some cases reinforced by specialists. They are nursed by the Territorial Nursing Service under an Advisory Council, with the aid of the St. John Ambulance Association and the British Red Cross. Of the *à la suite* staff 18 are called up on mobilisation, and of these, at any rate in the case of some of the London base hospitals, 4 captains are definitely resident medical officers, the principle of the rota not being adopted. The Territorial Base Hospitals were designed to receive patients from the Territorial army, and are like the hospitals of the Expeditionary Force at the rate of two for each division; but although mobilised primarily for this purpose they will be, and in some cases are now being, used to receive the wounded from the Expeditionary Force. The big civil hospitals which have placed beds at the disposal of the War Office are in most cases associated with these Territorial hospitals, and form the third accommodation for the wounded.

To return to the story of the wounded men. These having been collected as far as possible in accordance with the routine indicated by the orders for medical service in the field, are brought to Southampton and there distributed by the embarkation officer. Undoubtedly the most serious ones in the first instance have been kept at Netley. Of the rest some have been sent to other Permanent Military Hospitals, some to Territorial Base Hospitals, and some to one of the civil general hospitals whose beds are regarded as sections of the latter. From these hospitals they are in due course drafted into some of the many convalescent homes which have been placed at the disposal of the Government. As time goes on the probability is that more and more of the wounded will find their way into the Permanent Military Hospitals and Territorial Base Hospitals, as it is felt on all hands that it is not safe to surrender beds in the civil hospitals which may at any moment be wanted for the ordinary sick population. There is no reason to suppose that there will be less demand than usual on these beds, but the use of the permanent hospitals was in the first instance necessitated by the fact that the Territorial hospitals were not expected to be in existence until some short time after mobilisation of the Territorial Army.

These Territorial Base Hospitals are part of the organisation of the Territorial Force, or Second Line in our Army. As they were only to be called into being on mobilisation of the Territorials to minister to the wants of that force it was needless and would have been extravagant to fit up and maintain as going concerns institutions, of which there are 23 in Great Britain and Ireland, each with a complement of 520 beds, merely to await events. The primary steps which could be taken, however, were indicated.

The organisation of the Territorial Force is in the hands of County Associations, created *ad hoc*, consisting of the Lord Lieutenant of the county or other person selected by the Army Council, as president, and representative officers of all arms of the force, of county and borough councils, of universities, of employers and employed, and of coöpted members. This body supplies all requirements on mobilisation of the force, and is supposed to take note beforehand of what those requirements would probably signify.

Each Territorial Base Hospital has to house besides its complement of 520 patients a personnel of 112 officers and other ranks and 91 nursing staff, so that it may be imagined that to adapt buildings not designed for hospital purposes has been a huge task. An example drawn from one hospital will show what transformation may mean. The task was a stiff one, and it has been put through here with quickness and efficiency whether or no in accordance with any prearranged schemes or estimates.

The buildings selected were St. Gabriel's Training College and a Board School standing next it; the latter in the usual large asphalted playground, the former having about half an acre of garden in front of it. On taking over the premises from the college and school authorities the accommodation was roughly divided in accordance with the comparative size of the buildings by preparing a little over 200 beds in the college and a little over 300 in the school. Ways were made through the walls dividing the grounds. A great part of the internal structure of both buildings was immediately removed—cubicles, partitions, and educational fitments all disappeared, with the result that in each building there are now large airy wards holding from 20 to 30 beds, and smaller wards holding 10 or 15 beds. In this way the requisite accommodation for the patients was obtained, and the wards are very bright in appearance and perfectly fitted for their purpose. Next each building had to undergo complete sanitary rearrangement, and this was done partly by use of space acquired by removing the old appurtenances and divisions, but largely by the building on of sanitary annexes connected with the different floors. In this way a copious supply of bathrooms, sinks, special sinks for the emptying of bed-pans, and water-closets has been obtained. The Training College possessed an assembly or recreation hall in the grounds at the back, and this has been transformed into a very large ward, a lean-to annex supplying complete lavatory and sanitary accommodation having been added.

Similarly the cooking arrangements had to be entirely reorganised. The college was fortunate in possessing a large kitchen, an unusually spacious, well-planned room, and into this it was found possible to put new ranges, a large steaming apparatus, and all the appliances for dealing with not only the meals of the patients, but with the sergeants' mess, and to a certain extent with the officers' mess. A separate room was transformed into a kitchen for the nurses, while space was found for yet a third kitchen on an upper floor to further serve the officers' mess.

There has been nearly as much new construction as transformation, and some of the additions, notably the lifts and the annexes to the college, have involved serious constructional work, and have called of course for great alterations in water-supply and in lighting. Precautions for fire, of course, necessitated a change in water-supply. Both buildings were fortunately found to be adequately supplied with radiators.

The officers' quarters are situated in the college, and comprise a very small mess-room and bedrooms for the medical staff, and 20 beds for the use of sick officers. On the top floor of the college there is an excellently appointed operation theatre, X ray room, and a ward of seven or eight beds for the immediate use of patients who have been operated upon. In the basement of the college a chemical laboratory, which formed part of the original training equipment, has been easily turned into an excellent dispensary, and a small botanical laboratory next to it has become the bacteriological laboratory of the hospital. The Training College is finished, and the work in the Board School is so far forward that it is nearly ready to receive its complement of wounded.

The numerous new buildings in the roomy school yard for the use of the convalescent patients and of the personnel of the hospital have been erected with the completeness of the transformed main buildings. There is a large convalescent "dining hut" where the convalescent patients are to have their meals. Another large hut has been built for the quarters of the personnel, and contains a dormitory holding about 90 beds, and a mess-room with a small canteen for the men, a bedroom and messroom for the sergeants, with washing-places and baths. A covered way has been made between the buildings of the school and the college. A complete kitchen fitted with gas stoves occupies another building and serves the men's mess and the 300 beds in the school. A disinfector and a large steriliser have been erected in outbuildings, and an incinerator for the destruction of rubbish has been built. Other outbuildings in the yard comprise in addition to a guard room and store rooms of various kinds a mortuary and post-mortem room. An isolated permanent building forming part of the school, and used for defective children, has been altered to form an infectious block and is divided into two parts, so that separate infections may be dealt with.

The work that has been done here in transforming two civil buildings suddenly into a hospital capable of dealing with the medical and surgical wants of 520 persons with a personnel all told of about 200 has been very great. Taking it as typical of the kind of thing that during the last six weeks has been undertaken on all sides, we find in such work a satisfactory promise that the sick and wounded cases that reach, or occur in, this country will be well and promptly dealt with.

PROFESSOR BOSSI'S REBUKE TO GERMANY.

Professor L. M. Bossi, director of the Gynæcological Institute of the University of Genoa, has sent the following letter to the *Corpus Academicum* of the University of Leipzig and has furnished a copy of it to Emeritus Professor Sir Alexander R. Simpson, formerly professor of midwifery in the University of Edinburgh, who has been good enough to forward it to us for publication.

ESTEEMED COLLEAGUES OF THE UNIVERSITY OF LEIPZIG,—I received a copy of the special number of the *Leipziger Neuesten Nachrichten* accompanied by a letter which invites me to communicate to the University students and to the press of my country the contents of that journal with respect to the responsibility for this ruthless war. Then I read to-day the official notice that the Ministers of Public Instruction of the various German States have "by common agreement" forbidden the German universities to admit from this time forward as students Russians, Serbs, and Japanese. Thus, while on the one hand German university authorities rely on the principle of the internationalism of science for the defence of their own political position, they commit an act of university reprisal in striking opposition to that principle. The contrast of these two actions at the expense of the prestige of science and of the dignity of its cultivators is too evident to require any further comment; but it obliges me to break the silence which I had imposed on myself, and to open my mind to you with loyalty and frankness, as I hold that to be now a duty imposed on me by my position as a university professor.

Science has no confines; its country is the world. If this principle had been present to your mind, my esteemed colleagues of the University of Leipzig, I am sure that you would have avoided any attempt to implicate your colleagues of the Italian universities in a conflict of brute force, from which science and its cultivators ought to remain entirely aloof, in order to preserve, in the midst of the present unexpected return to barbarism, at least one patrimony of mankind pure and unspotted—that of the intellect.

But, since you have attempted to invade this field also, it is my bounden duty to reply to you that while we were such admirers of your advances in the immense fields of the positive sciences and of your scientific method as to recognise almost at a glance a true and peculiar hegemony of your nation, we cannot admire, much less approve, the horrible fact that has to-day come unexpectedly to light—emerging in all its terrific concrete reality—of the premeditated concentration of a great part of the scientific and intellectual energies of your nation to bring about the triumph in the world of the dominion of brute force.

In our academies we shall teach our studious youth the great benefits that all mankind have derived from the experimental method of science, which, initiated in Italy, received its largest development and reached its highest prestige in Germany. They will learn that the Latin peoples have owed much to the applications of disciplined German method in all spheres of life and in all branches of human knowledge. They will learn that the Latin genius has been largely assisted in its positive manifestations by the practical methodicalness of Germany; that Germany has contributed perhaps more than other nations to the application and the diffusion of Italian scientific initiative (a fact which I also am personally bound to affirm), and that for this we ought to retain gratitude.

But faithful always to the great principle that the prosperity and happiness of the peoples can be founded only upon human brotherhood, we shall not be able to approve:

1. The incitements to the use and abuse of violence and of brute force which your Chancellor gave in full *Reichstag* with a cynicism which revolted the consciences—in your opinion perhaps too sentimental—of us Latins.
2. That for years peace is preached, while human slaughter is being prepared instead, and while even the hospitality of many European centres is being sterilised by the preparation there of arms and of nuclei of men ready for treachery.
3. That—an example almost unique in the modern history of the peoples—International Treaties are trampled on, and such neutral States as Luxemburg and Belgium are invaded; unarmed peoples, destined by the law of nations exclusively to peace and to labour, being attacked unexpectedly and with unheard-of and (as the facts will demonstrate inexorably) premeditated violence.
4. That villages and also cities of such neutral States are burned and destroyed, without any respect either to the rights of property or to patrimony sacred to art and to civilisation.
5. That open and tranquil cities are bombarded at night, without any respect to the inviolability of the asylums of the infirm.
6. That unarmed citizens are slain, solely because bound by affection to their native land.

It is a civilisation wholly different from this that we feel it to be our duty to teach in our universities and to our studious youth, who from the very fact of our absolute neutrality, imposed by our people and approved by their present government, will learn that Italy desires the restoration of a civilisation of scientific and social progress founded not in the dominion of violence but of human solidarity in the brotherhood of the nations.

(Signed) Prof. L. M. BOSSI,
Genoa, Sept. 10th, 1914. of the Royal University of Genoa.

Prof. Bossi, in a covering letter to Sir Alexander Simpson, says: "Our science, which has for its object the physical and psychical maintenance and amelioration of the human race, cannot remain indifferent to the terrible tragedy that is being enacted. I believe it to be our duty to protest against the erection of brutal force into a system of domination predestined to the physical and moral ruin of the peoples. The letter which I have sent to the professors of Leipzig represents, I am convinced, the sentiments of the majority of my colleagues in Italy."

MEDICAL CASUALTIES AT THE FRONT.

The following additional casualties to officers of the Royal Army Medical Corps on active service have been reported:—

Killed: Lieutenant Herbert Leslie Hopkins, Lieutenant John Forbes O'Connell, and Lieutenant James Laidlaw Huggan. Lieutenant-Colonel Charles Dalton and Captain Henry Sherwood Ranken are reported to have died of wounds. *Wounded:* Captain B. H. V. Dunbar, Lieutenant R. Fisher, and Captain C. T. Edmunds and Lieutenant E. R. Walker, who were previously reported missing. *Missing:* Captain S. Field, Captain M. P. Leahy, Captain G. H. Stevenson, and Captain C. W. Holden, who was previously reported wounded.

The following officers previously reported missing are now unofficially reported prisoners of war:—Major J. H. Brunskill, Captain E. S. B. Hamilton, Lieutenant A. J. Brown, Lieutenant H. W. Hills.

The following officers previously reported missing have since rejoined: Captain H. C. Hildreth, Lieutenant J. H. Bell, and Lieutenant F. H. Tulloch.

MISUSE OF THE RED CROSS.

The War Office has issued the following warning this week:

> In view of the large number of cases where the Red Cross is being improperly used by persons presumably ignorant of the statutory prohibition of such use, the public are warned that, under the Geneva Convention Act, 1911, it is not lawful for any person to use for the purposes of his trade or business the emblem of the Red Cross on a white ground or the words "Red Cross" or "Geneva Cross." Any person acting in contravention of this provision is guilty of an offence against the Act, and liable on summary conviction to a fine not exceeding £10 and to forfeit any goods upon or in connexion with which the emblem or words are used.

The Act in question is the legislative measure agreed to by each of the Governments participating in the Geneva Convention of July 6th, 1906.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE POSITION OF STUDENTS.

AT an extraordinary Comitia, held on Sept. 24th, Sir Thomas Barlow, Bart., K.C.V.O., the President, being in the chair, a report, dated August 14th, was received from the Committee of Management referring to the decision to hold an additional final examination commencing on Sept. 8th, and to the special conditions which applied to the candidates entering for the examination. The Committee of Management also successfully recommended the adoption of the following temporary regulations, viz.:—

1. That time spent as assistant on active service in one of His Majesty's ships or in a naval or military hospital or any hospital utilised by the naval and military authorities not exceeding six months be allowed to count for the equivalent period of medical and surgical hospital practice and for three months each of the required period of medical clinical clerkship and surgical dressership, provided that a satisfactory certificate is produced from the principal medical officer under whom the assistant serves.
2. That medical clinical clerkships and surgical dresserships served before second examination in anatomy and physiology has been passed be recognised.

THE CARE OF THE SICK AND WOUNDED ON THE CONTINENT.

The Order of St. John of Jerusalem is prepared to receive further applications from surgeons who are anxious to help in the treatment of the sick and wounded in temporary hospitals on the continent. Applications for particulars of service may be made to St. John's Gate, Clerkenwell, London, E.C., to Mr. H. T. Watson, or to the chief surgeon of the Brigade, Mr. Edmund Owen, 24, Upper Berkeley-street, Portman-square. W.

Sir Anthony A. Bowlby, C.M.G., surgeon to St. Bartholomew's Hospital, has gone to France, at the request of the War Office, to join the staff of the principal medical officer of the British Expeditionary Force as consulting surgeon.

PROTECTIVE TREATMENT AGAINST TYPHOID FEVER.—The Research Defence Society has issued a popular leaflet explaining the great value of this treatment. It has also arranged for the treatment to be given, to anybody desiring it, at the society's office. Supplies of the leaflet can be had on application to the honorary secretary, 21, Ladbroke-square, London, W. Telephone 975 Park.

THE WOMEN OF CANADA AND THE WAR.—H.R.H. the Duchess of Connaught has announced the collection by the women of Canada of over £57,000 for the use of the British War Office and the Admiralty. Of this amount £37,000 will be handed over to the Admiralty for the establishment of a Naval Hospital at Portsmouth. The balance of £20,000 will be placed at the disposal of Lord Kitchener.

THE FIFTH SOUTHERN TERRITORIAL HOSPITAL.—This general hospital is established in a council secondary school in Fawcett-road, Southsea, near Fratton Station on the London and South-Western Railway, from which the sick and wounded arriving from Southampton are easily brought to the hospital. The following physicians and surgeons form the staff:—Lieutenant-Colonels: John Kyffin (in command), C. P. Childe, and C. F. Routh. Majors: E. J. Davis-Taylor (permanent personnel), T. A. Munro Forde, John Phillips, C. A. Scott Ridout, and R. A. Dove. Captains: H. B. T. Morgan (permanent personnel), Harold Burrows, W. P. McEldowney, P. H. Green, J. L. Wright, C. Lamplough, W. Carling, H. L. Driver, S. Goss, J. Blackwood, M. H. Way, and M. Dale Wood. There are in this hospital at present about 320 British wounded and sick, the number varying daily as men are discharged to their depôts as fit for duty. There are 95 Germans, mostly cases of serious wounds, and five German officers, including three doctors. The Germans are being treated exactly as our own men, except that they are not allowed to write or receive letters. Their behaviour is good. Few of them seem to have any idea of the real state of affairs so far as the war is concerned. The experiences of a hospital are mostly grave, but an amusing incident occurred lately. A German was ordered medicine. Fearing it was poisoned he insisted that the nurse should take a dose before he would do so. Four deaths have taken place, two from acute tetanus, one from encephalitis consequent on hernia cerebri, and one from pneumonia. The nurses have undergone antityphoid inoculation.

CANADA'S GIFT TO THE RED CROSS.—The Dominion Government of Canada, Ottawa, has transmitted the sum of £10,068 9*s.* 10*d.* from the Canadian Red Cross branch to the funds of the British Red Cross Society, and Queen Alexandra has sent by cable a message of warm appreciation for this munificent contribution to the funds of the society.

EDINBURGH IN WAR TIME.—Our Edinburgh correspondent writes: A number of wounded soldiers arrived in Edinburgh in the early morning of Sept. 28th, and were conveyed by motor ambulances to Craigleith Hospital. At a meeting held in Edinburgh on Sept. 19th, at the residence of Lord Kinross, the chairman, a committee was formed for the purpose of dealing with the Belgian refugees in Edinburgh and district. Among those who attended the meeting were the Marchioness of Bute, Dr. Sarolea, Belgian Consul in Edinburgh, Mr. Campbell Gibson, Belgian Consul in Leith, and a number of representative citizens. Lady Bute intimated that she had interviewed Belgian Government officials in London, and arrangements had been come to authorising Mr. Campbell Gibson to divide parts of the proceeds of funds being raised towards the maintenance and housing of any refugees who may come to this district. It was also intimated that a number of private individuals were prepared to receive a certain number of refugees into their homes, and a certain institution had offered to accommodate the refugees until they had been allocated to private houses. The first relay of refugees are expected to arrive in Edinburgh this week. Recruiting has gone on very briskly in Edinburgh, and still continues, the numbers joining being steadily maintained. The committee of the Edinburgh Lying-in Institution, 58, Lauriston-place, have decided to give medical attendance and nursing gratuitously to the wives of soldiers and reservists at their own homes during the continuance of the war.

NORTH TYRONE ULSTER VOLUNTEER HOSPITAL FOR FRANCE.—Our Belfast correspondent writes: A North Tyrone Ulster Volunteer Force Hospital has been accepted for service at Pau by the French Government, and will leave as soon as its equipment can be completed. The French Government will support the hospital when established at Pau, but the cost of equipment and transport have to be raised. Several Irish medical men have volunteered to the War Office to give their services at the front, but the reply so far has been that they are not required. The principle of bringing home all the wounded who are fit to travel may make the need of doctors or nurses at the front much less, but there must be a great deal of work to do.

AMERICAN WOMEN'S HOSPITAL AT PAIGNTON.—Mr. Paris Singer has placed his residence, Oldway House, Paignton, at the disposal of the executive committee of the American Women's War Relief Fund, and it has been fitted up as a hospital, with operating theatre, &c., for the treatment of wounded sailors and soldiers of any nationality. It will accommodate 200 patients, and 70 more beds can be added if required. The largest ward contains 67 beds, and was formerly the banqueting hall. The hospital has been accepted by the War Office and is being worked by the British Red Cross Society, and is now ready for the reception of patients. The hospital staff is as follows: Principal medical officer, Mr. J. Ernest Lane; consulting physician, Sir W. Osler; honorary physicians, Dr. A. E. Carver and Dr. W. W. Stabb; honorary surgeons, Sir R. Hampden Smith and Dr. Lawrence H. Bennett; dental surgeon, Mr. G. K. Mallory; radiographer, Mr. W. H. Steele; anæsthetists, Mr. F. T. Frampton and Mr. H. C. Adams; resident medical officer, Mr. Rupert Farrant.

THE Devon Volunteer Aid Organisation has fitted up the Episcopal Modern School for Girls at Exeter as a hospital. It contains 90 beds, and this number can be increased to 110 if necessary. The building has an operating theatre, dispensary, &c. The officers and staff have been appointed, and these include Mr. Worthington as commandant and Dr. J. S. S. Perkins and Mr. G. Adkins as medical officers.

THE BRITISH RED CROSS.—Mr. Percy Sargent, surgeon to out-patients at St. Thomas's Hospital, has gone to Rouen to take charge of the surgical division of the British Red Cross Hospital in that city. The other medical officers attached to the Red Cross unit at Rouen are Dr. F. J. Barker, Dr. A. M. Ware, Mr. A. G. Hebblethwaite, and Dr. C. R. Howard.—The society has accepted the offer of the use of 50 beds at the Cancer Hospital, Fulham-road, S.W.

A SUM of £460, contributed by the employees of Messrs. Siemens Brothers and Company at Woolwich works, has been handed to the Mayor of Woolwich for the Prince of Wales's Fund.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—As the result of the special examination held on account of the war the Royal College of Physicians and the Royal College of Surgeons at their meetings on Sept. 24th conferred diplomas of L.R.C.P. and M.R.C.S. upon 122 candidates (including eight ladies) who have completed the Final Examination and have complied with the respective by-laws. The names and medical schools of the successful candidates will be published later.

PRESENTATION TO CRAIGLEITH HOSPITAL.—Through the kindness of Mr. William Guy, surgeon in charge of the dental department of the hospital, a complete dental equipment has been furnished to Craigleith Hospital, Edinburgh.

TO BELGIAN MEDICAL MEN.—Medical men among the Belgian refugees who can speak French, Flemish, and English are requested to communicate with the Belgian Relief Committee, 10, Finsbury-square, E.C., as their services are much needed at the various hostels.

Kennard.—On Sept. 25th, at Bedford-square, W.C., the wife of Dudley Kennard, F.R.C.S. (*née* Hoffmann), of a son.

Tresidder.—On Sept. 25th, at Stratton-terrace, Greenbank, Falmouth, the wife of Mr. S. L. Tresidder, L.D.S. Eng., of a son.

MARRIAGES.

Colebrook—Campbell.—On Sept. 24th, at St. Stephen's Church, Gloucester-road, Leonard Colebrook, M.B., B.S., Captain R.A.M.C. (T.), to Dorothy, youngest daughter of the late John Scarlett Campbell, I.C.S., and Mrs. Scarlett Campbell.

Hall—Slatter.—On Sept. 22nd, at St. Andrew's, Wells-street, W., George Hall, M.D., to Bessie, youngest daughter of the late John Slatter, of Adelaide, South Australia.

Welch—Skinner.—On Sept. 26th, at St. Luke's, West Norwood, Horace Rexford Welch, M.D., eldest son of Samuel Welch, M.D., to Dorothy Eunice, daughter of the late Rev. Henry Skinner, M.A., of Geelong, Victoria.

DEATHS.

Armstrong.—On Sept. 15th, in France, from wounds. Arthur Keith Armstrong, L.R.C.P., M.R.C.S., Lieutenant R.A.M.C., aged 33 years.

May.—On Sept. 23rd, at his residence, High Cross, Tottenham, Edward Hooper May, M.D., F.R.C.S. Eng., in his 83rd year.

Peel Ritchie.—Accidentally drowned at Granton on Sept. 24th, Lionel Charles Peel Ritchie, Ch.M., M.D., F.R.C.S.

Thomson.—On Sept. 27th, at a nursing home, Sir Alfred E. Thomson, M.D., of Cape Town.

Turner.—On Sept. 26th, at Springfield, Upper Clapton, Frank Edward Turner, M.R.C.S., L.S.A., aged 73 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

During the continuance of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

THE WISDOM OF ANIMALS.

To the Editor of THE LANCET.

SIR,—Your note last week under this heading prompts me to remind your readers that undoubtedly the endowment by popular consent of certain animals with certain qualities was the reason for much of the fanciful ancient pharmacy; the underlying idea was that the exhibition of potions of the animal as a drug would endow man with the characteristic qualities of the animal. Animal remedies from the earliest times have proved the anthropomorphising tendency. The toad was ugly from the human point of view; therefore it was venomous, and in the late eighteenth century Gilbert White, of Selborne, had heard of a quack doctor eating toads whole either to prove that they were not poisonous or that he was poison proof. The toad really forms part of the ancient pharmacopœia, which doubtless regarded it as a poison. All the drugs derived from the intestines or brains of quadrupeds and birds by our ancestors were sanctioned by fanciful human attributions. The flesh of certain birds was supposed to promote swiftness. The flesh of the lion, if procurable, was believed to infuse valour into the eater. Portions of goat were eaten in order to strengthen procreative powers. The superstitions concerning the animals being multifarious the composition of the various potions and electuaries became complicated in consequence. The jokers of old time who impressed their stories upon tribal credulity were responsible for this preposterous pharmacy. The persons who tell these stories nowadays to credulous editors are responsible for a certain amount of irritation. They have their joke, but they help to create a sentimentality which may be actively mischievous.

I am, Sir, yours faithfully,
A SERIOUS PERSON.
Sept. 28th, 1914.

MODERN MEDICAL POETS.

IT is well to have among us, now as of old time, a few disciples of Æsculapius on whom at their birth Melpomene has glanced with tranquil eye. Mr. Augustus H. Cook, M.B. Lond., has published through Messrs. G. Bell and Sons, Limited, a little volume of verses called "Eve Repentant and Other Poems." Though perhaps the verses are of somewhat unequal merit, they contain some good description, some picturesque flights of imagination, and in some of the verses a deep religious feeling smoothly and lucidly expressed. Major Greenwood, M.D., LL.B., in "London, an Historical Poem" (originally printed in the June issue of the *City of London Illustrated*), traces, in nine-lined iambic pentameters, the last line being an Alexandrine, the rise and development of London in its main incidents and conditions. It contains reproductions of the Steel Yard and neighbourhood, from Van Wyngard's plan taken for Philip II. of Spain, and a map of London from Lincoln's Inn to the Tower, circa 1658. Yet a third medical writer of verse is Dr. F. Barber Wells, for whom Messrs. W. H. and L. Collingridge, 148, Aldersgate-street, have published (in khaki uniform with red facings) two war poems, which, we are informed, are "sold for the benefit of the Prince of Wales's National Relief Fund." The first, entitled "1914," is a sonorous ode on the war in the cadence of Gray's Elegy. The second, "The Roll of the Drum," has a swinging rhythm that well suits the subject.

THE LIBRARY OF THE MEDICAL SOCIETY OF LONDON.

Mr. George Bethell's "Account of the Library of the Medical Society of London," which has been reprinted from the *Library Association Record* for May, contains a note on Dr. John Lettsom, the founder of the library, and recounts the history of the library with not a few interesting *obiter dicta*. It is true, for instance, that "the principal part of our knowledge must be ever derived from comparing our observations with those of others." Mr. Bethell quotes four variants of the well-known epigram on Lettsom. We learn that Dr. James Sims, who managed to be selected president of the society for 20 years, in 1800 succeeded in selling to the library a large number of books, for which he received £500 cash down and an annuity of £30 a year for himself and his wife. A very interesting MS. in the library is the diary of Dr. John Ward, vicar of Stratford-on-Avon, who had practised medicine. One entry therein is worthy of special note: "Shakespear, Drayton, and Ben Jhonson (*sic*) had a merry meeting, and it seems drank too hard, for Shakespear died of a feavour there contracted." The living wage and discrimination against married employees appear, from the rules formulated by the committee on Jan. 25th, 1780, concerning the duties of an "under library keeper," to have been live questions even in those days, for it is stated that this official should be "rather a single person than married," and that he may have "a *sufficient salary* for his subsistence." The library contains some valuable incunabula and an excellent collection of Early English printed medical works of the sixteenth and seventeenth centuries, including a reprint from the only copy of the original edition of Servetus's "De Trinitate Divini" that escaped being burnt with its author by Calvin. Nearly all the copies of this reprint were burnt by Dr. Gibson, Bishop of London.

THE RAGGED SCHOOL UNION AND THE WAR.

To the Editor of THE LANCET.

SIR,—This great crisis in the life of our nation has involved the withdrawal from our ranks of hundreds of men who have either joined the Territorials or enlisted, and there is immediate necessity for wholehearted men and women to volunteer as workers in filling up the gaps that the physical, social, and religious welfare of the children may not suffer. It is of the utmost importance to the nation that our 140 affiliated schools and missions should be maintained at their normal strength. It would be appalling to contemplate the state of our city poverty areas without such centres of light and healing.

Our holiday homes, also, at Southend, Margate, Bognor, Bournemouth, and Windsor will be used throughout the year for poor cripple children suffering from serious complaints and who are quite unable to face the ordinary conditions of London life. Many of our missions in populous centres are rendering national service by allowing their premises to be used by the Soldiers' and Sailors' Families Association, day clubs for unemployed boys, workrooms for girls and women, &c. All this, however, costs money—£100 a day is needed—and the measure of our ability to meet the dire need surrounding us is exactly the measure of the generosity of the public.—We are, Sir, yours faithfully,

JOHN KIRK, Director.
ARTHUR BLACK, Honorary Secretary.
32, John-street, Theobald's-road, London, W.C.,
Sept. 25th, 1914.

SURGICAL INSTRUMENTS FOR SALE.

WE publish this week an advertisement offering for sale a complete set of surgical instruments and operating equipment. We know the circumstances in which the articles are for sale, and think that some of our readers might like to call the attention of the public to an opportunity that is being offered to them, at a time when gifts of this nature are being generously made for the assistance of military and Red Cross hospital organisation.

RABIES AND MUZZLING IN NEW YORK.

THE prevalence of rabies in New York recently led the Committee on Infectious Diseases of the Advisory Council of the New York Department of Health to adopt a muzzling order. The Commissioner of Health publishes in the *Weekly Bulletin* of the Department for Sept. 5th a series of extracts from the variegated correspondence that has poured in on him since the enforcement of the order. While much of it is commendatory, one writer has the temerity to assert that "there is no such thing as mad dogs or people being bitten." The logical faculty of one writer can be estimated from the remark, "Surely an occasional mad dog will not lead you to condemn the whole race any more than an occasional insane human leads us to ask what is the use of any of us." Even in New York, however, dangerous insane humans are confined where they can do no harm. Another writer says that "you may as well banish children" as dogs. Fortunately the majority of correspondents seem to entertain more reasonable views.

MILITARY SURGERY IN THE BALKANS.

J. A. H.—The following two papers appeared in THE LANCET last year:—"Some Surgical Experiences during the Balkan War," by Sidney Smith (May 31st, 1913), and "Medical and Surgical Experience in the Balkan War," by C. Max Page and S. V. Appleyard (July 19th and 26th, 1913). A book entitled "With the British Red Cross in Turkey, 1912–13," by A. Duncan-Johnstone (London: J. Nisbet and Co. Price 5*s*. net) was reviewed in our columns on May 31st, 1913.

THE Scholl Manufacturing Company have offered to the War Office 2000 pairs of their "foot-eazers" for the use of the troops now serving abroad and for those who may shortly be called upon to take their places in the fighting line. It is claimed that these arch supports have a very restful effect upon the feet when engaged in long marches.

◆

Englishwoman.—Our correspondent is mistaken. Medical practitioners do not "accuse" their patients of hysteria any more than they "accuse" them of tuberculosis. To speak of a "determined and sustained charge of hysteria" puts the matter in a grotesquely wrong light.

Subscriber.—We think 10*s*. 6*d*. a reasonable fee for examination and report.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. T. Gray: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Addison: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. T. Gray: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Addison: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. E. Batten: Syringomyelia.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. G. Stewart: Localisation of Cerebral Tumours.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: The Skin in Health and Disease.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Puerperal Infection. 11 A.M., Examination of Patients and Minor Operations.

TUESDAY.—10 A.M., Major Operations.

WEDNESDAY.—10 A.M., Obstetrical Lecture: Puerperal Infection (continued). 11 A.M., Examination of Patients and Minor Operations.

THURSDAY.—10 A.M., Major Operations.

FRIDAY.—10 A.M., Gynæcological Lecture: Injuries of Labour (continued). 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT [illegible] REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months ... ... —	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Wilcox and Co., Lond; Warrington Infirmary, &c., Secretary of; Wolverhampton, &c., General Hospital, Secretary of; Messrs. J. Wright and Co., Birmingham; Mr. F. Wilson, Lond.; Mr. D. L. Williams, Cardiff.

Y.—Dr. M. Young, Chester.

Z.—Messrs. A. and M. Zimmermann and Co., Lond.

An Address

ON THE

PATHOLOGY OF HEART FUNCTION.

Delivered at the Pathological Section of the British Medical Association Meeting, Aberdeen,

BY THOMAS LEWIS, M.D. LOND.,
F.R.C.P. LOND., D.Sc.,
PHYSICIAN, CITY OF LONDON HOSPITAL; ASSISTANT PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—With your assent I propose to confine my observations within certain bounds, and to deal with questions to which answers have been eagerly and widely sought during the past few years in this country. My remarks will be concerned with those curious disorders of the heart's action which are disturbances of the regular sequence of chamber contraction.

THE RESULTS OF RECENT WORK.

At the outset let us detect and isolate the first chief product of recent work. From the accumulated study of the past few years springs the knowledge that the mechanism of the human heart beat may be perturbed in one of several chief ways; each is now distinctly recognisable in the patient, each may be reproduced in the experimental animal. To that extent each is clearly understood. Phenomena with which we had to deal, the meaning of which was unknown to us, are now, thanks to this work, clearly and indisputably known to result from defined changes in the action of the heart. The identification of the types of cardiac irregularity has been a first and great advance. It is an advance which has been taken with security and finality. That the action of the human heart may be disturbed by sinus arrhythmia, heart-block, extrasystole, simple paroxysms of tachycardia, auricular flutter, auricular fibrillation, and alternation of the ventricle is known beyond all reasonable doubt. This analysis forms no longer a centre for discussion; it is, perforce, the first and generally accepted foundation for discussion. I pass, then, from such questions as the reasons for irregularity of the heart, affirming that the problems which concern themselves with the kinds of these disorders are solved. Excepting a few of the rarest and least important disturbances, the analysis of disordered heart action has ended.

The inquiry proceeds to its second stage—search for the causes of the named disorders. So far as we are able, let us carry forward our certain knowledge of the existence of these disorders and study them impartially, freed from the constructed hypotheses which already closely surround them. There is, so I think, one hypothesis in particular which impedes us, and Wenckebach, to whom we owe so much for our knowledge of these disorders, is in the first place responsible for it. It is the attempt to correlate these disturbances of the heart's action with perversions of those hypothetical functions of heart muscle to which Engelmann pledged his faith. While Gaskell first demonstrated that certain attributes of heart muscle are affected in varying degree by such procedures as stimulation of the great heart nerves, Engelmann followed him and attempted a nicer delimitation, regarding these attributes as isolated and strictly separate functions. To accept the doctrines of Engelmann's school is to accept the view that rhythmicity, excitability, contractility, and conductivity are functions of muscle so independent that each has a distinct chemical process underlying it. Now it is not within the proper range of pathological speculation fully to discuss the merits or demerits of this doctrine, which has attaching to it a fatiguing Greek terminology of its own, but it is within our province to consider if such doctrine is acceptable as a basis for pathological thought. I would remind you that it is a departure not only from general but from special physiological teaching in this country. Gaskell was at much pains to emphasise, not so much the varying effects of vagal stimulation upon different qualities of muscles, but the special endowment of certain regions of the heart with different qualities. It was to the junction of sinus and auricles and to the junction of auricles and ventricles that he pointed as to tissue specially endowed with rhythmic properties; it was to these same tissues he attributed a less highly developed power of conducting impulses. The important divergence of these trains of thought, that of Gaskell and his successor, has been insufficiently appreciated in the pathological world.

The observations of these earlier workers were undertaken upon the lower orders of the vertebrate heart; we as pathologists deal finally with more highly organised structures. I would lay stress on this consideration, that valuable as is the knowledge of the amphibian and reptilian heart, valuable especially in guiding us to a true appreciation of the more fully developed organ, we should never forget that our real business is with the mammalian heart, and that the basis of pathological argument should be a basis of mammalian anatomy and physiology; these sciences form the actual connecting links between pathology and the more elemental sciences.

HEART FUNCTION IN RELATION TO DISTURBED HEART ACTION.

I return to the question of heart function in its relation to disordered heart beat. Sinus arrhythmia is, as you know, a disturbance of the heart's rhythm at its source—an irregularity of the whole organ. Is it justifiable to classify it as a disorder of rhythmicity? Remember that the term rhythmicity, as we are now using it, is a special term, used to designate a function of heart muscle generally. Have we to deal with a change in this general property of the heart muscle as a whole? We may or we may not; there is little or no evidence. But the facts are these. The mammalian heart beat originates in the immediate vicinity of a small and specially constructed mass of tissue, the sino-auricular node. Indeed, it is now a generally accepted view that this node originates the mammalian heart beat; we may regard this node as one of a few collections of tissue specially endowed in Gaskell's sense with the property of rhythmic impulse formation. Cool this node, the heart rhythm is retarded; destroy the node, the natural rhythm of the heart is lost. Are such disturbances to be regarded as disturbances of rhythmicity? In the last case evidently not, for we deal with local destruction of tissue. Similarly in auriculo-ventricular heart-block, where we deal with minor changes in the facility of impulse transmission, we might hesitate to deny the affection of a function "conductivity" in specific instances; but when that slender strand, the auriculo-ventricular bundle, is broken, transected by the growth of abnormal tissue or by injury, we may not think in terms of altered functions, we must think perforce of tissue damage.

My thesis is that we have no direct knowledge of disordered "rhythmicity" or disordered "conductivity," &c., in the human heart, using these terms in their special senses, and that Wenckebach's classification of irregularities of the heart, based as it is upon Engelmann's hypothesis, rests upon an insufficiently secure foundation. The dangers of the functional hypothesis cannot and have not been avoided. Gaskell's argument, pointing as it does to specific regions of the heart, gives us a safer direction.

Yet it appears questionable if a purely physiological or purely anatomical basis can in the end serve us. Pathology must take count of new factors. In Wenckebach's classification extrasystoles are forced into the category of disturbed "excitability." Now excitability is the power of the heart to respond to external stimuli, electric, mechanical, or chemical. Its degree is measured by testing the strength of the threshold stimulus. That spontaneous extrasystoles are forced by some abnormal stimulus acting upon a hyperexcitable ventricle is a supposition for which no evidence has been adduced. On the contrary, there are conditions in which excitability, electrically tested, is depressed, and in which these beats are prevalent (notably in poisoning with potassium chloride). It is not in the quality excitability that the change is to be sought, but rather in the forces which explode the developing contraction. We know of no process in the working of the normal heart which in any way resembles the shock used to test excitability; in forcing a contraction this shock usurps the normal process of stimulation by anticipating it. In the extrasystole there is some similar agency at work; good ground can be taken for the belief that the stimulus is of an abrupt kind, that it is not a hurrying of normal impulse formation; but that it is of a kind as foreign to the physiological organ as is the induced current.

These preliminary considerations I have dwelt upon at some length because I think it of great importance at the outset we should have clear and solid ground upon which to stand. Consider the separate disorders of the heart's mechanism in terms of function and you veil them with mental concepts of an unstable and elusive, if not delusive, nature; consider them as simple facts and treat each upon its own merits, and you have rock beneath your feet. Briefly, my view is that pathology as a science is safe when it leaps from the *facts* of physiology; but that its footing is precarious when its take off is the physiological hypothesis. The remaining part of my paper will conform to this point of view; I propose to discuss a few of the problems which are suggested by contemporary observations, and which are concerned with separate disorders of cardiac mechanism.

AURICULO-VENTRICULAR HEART-BLOCK.

I have said that the existence of auriculo-ventricular heart-block in man, the subject of disease, has been abundantly proved; it has been proved in its many grades. It seems to me also that we can point, without fear of contradiction from facts, to the cause of this heart-block in a large number of our patients. There is to my mind no doubt from our evidence that the sequence of the contractions of auricle and ventricle is normally and wholly maintained through the medium of the auriculo-ventricular bundle; and that structural damage which completely breaks this slender tract is responsible for a number of instances of complete dissociation. It is not my present intention to discuss this evidence, for I have done so somewhat fully in another place. But I may remark upon the significance of these observations. The heart-block which so arises is engendered neither by an affection of "conductivity" nor by an original lack of conductive power on the part of the tissues involved. It is the result purely of accident, the division by disease of the conducting fibres, concentrated in a slender tract. In many of those instances where, though complete dissociation has been present, the lesions found after death but partially break the anatomical continuity, a similar explanation may be quite rationally held, for here we may assume complete loss of function even though there is but incomplete loss of structure; meaning by function not the single function of "conductivity," so called, but all function. But likewise instances are on record of complete dissociation in which no lesions have been discovered in this tract, and I may be allowed briefly to relate a few reflections upon these types of heart-block.

Experimental heart-block may be obtained in one of three chief ways: (1) by direct interference with the conducting tracts; (2) by stimulation of the vagus nerve, directly or indirectly; and (3) by the introduction of poisons into or by altering the metabolites of the circulating blood. That heart-block is induced in the human subject by similar disturbances is known. It follows when a calcareous or gummatous mass or malignant growth invades and divides the tract; it can be produced by pressure upon the vagus in the neck; it occurs in asphyxia when the heart is dying. But it is a moot point if long-continued heart-block of high grade is ever produced in the human subject by purely nervous or purely chemical influences. There are no unquestionable records of the complete though temporary removal of such heart-block by the administration of atropine, though the test has often been applied, and experimental heart-block of high grade and resulting from poisoning can be induced only where the heart is reduced to a nearly moribund state. For these and other reasons my own feeling is that persistent heart-block of high grade is invariably the result of a local tissue damage or that there is some cause of heart-block with which we are as yet totally unacquainted. It may be that our histological methods are still too imperfect to demonstrate conspicuous lesions, as they were in the nervous system before the discovery of Wallerian degeneration.

Temporary heart-block in man, on the other hand, is to be explained on the grounds of nervous influence or chemical change in some instances. In what region of the heart are such influences felt? In some recent experiments, in conjunction with Dr. J. Meakins and Dr. P. D. White,[1] I have been able to return a partial answer to this question, and the answer conforms to Gaskell's teaching. The vagus in producing heart-block acts upon the region of the conducting tissues in the immediate neighbourhood of the a.-v. node. So also does the single poison tested, a product of asphyxiation. Unquestionably this region of the conducting tissue is a susceptible point, a natural blocking point. This and other evidence supports the conclusion that heart-block, produced in one of the three named ways, is conditioned by interference, be it through direct, nervous, or chemical channels, with the auriculo-ventricular conducting system, and especially with the auriculo-ventricular node and bundle.

---

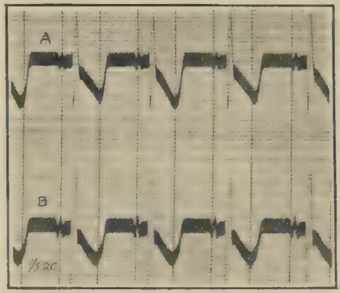
PREMATURE CONTRACTIONS AND ALLIED DISORDERS OF THE HEART'S RHYTHM.

There are several disorders of the heart's action which are very closely related. I refer to premature contractions (or extrasystoles), to paroxysmal tachycardia, to auricular flutter, and to fibrillation. It is well known that in patients who suffer from attacks of either one of the three last-named disturbances premature contractions are common in the intervals between the attacks; they are especially common when the attack is pending, or immediately at its offset. In experiments almost any interference which will produce one or other of the graver disturbances will when moderated produce the extrasystole. Influences which abate the greater, for example flushing the heart with blood in anæmic subjects by pressing on the abdomen, or the injection of small doses of potassium chloride in animals, will also abolish the lesser malady. In many patients who are the subjects of extrasystoles these beats are not isolated; the interruptions of the heart's rhythm may for periods be by single premature beats, but here and there one disturbance is quickly followed by a second; the extrasystoles are coupled. In the same or other patients groups of three or more such beats may be seen from time to time, though the customary event in these hearts is the solitary interruption. Now if we consider the solitary beat and the first of a short run of beats, we can discover no difference between them by any of our methods of examination. Both start prematurely, both originate in the same focus, and this focus is almost always an abnormal one; it may be in auricle, it may be in ventricle. The events which succeed the disturbance differ, but only because in one case the same event is repeated. If we examine the effects of the solitary beat upon the subsequent beating of the heart we discover essentially the same effects as those which follow the last of a short succession of such contractions. The conclusion is, I think, inevitable—namely, that the solitary extrasystole and the individual beats of a short run are of the same nature. A precisely similar conclusion applies to extrasystoles and to individual beats of a long-continued paroxysm of tachycardia. If, as is often the case, the short run of beats is continued for 10, 15, or more cycles, the phrase "run of extrasystoles" is no longer applied to it; the disturbance constitutes the simplest form of paroxysmal tachycardia. In other words, there is no real dividing line; there is no essential distinction to differentiate the run of two or more extrasystoles from a paroxysm of tachycardia which lasts for many hours. Clinical and experimental evidence show the same want of definite boundary between the paroxysmal tachycardia and auricular flutter; here the distinction is chiefly one of heart rate, and this passes through all gradations. Lastly, the same conclusion applies to paroxysmal tachycardia or flutter and the more complex conditions called fibrillation.

Let me for purposes of illustration describe the response of the ventricle while this organ is under the influence of gradually lightening chloroform anæsthesia, for the events and their progress are very striking. The first disturbance may come with solitary extrasystoles arising at a recognisable focus (say A) in the ventricle; it is followed by similar extrasystolic interruptions from other foci (recognisable as coming, we will say, from B and C); the extrasystoles of these types become grouped, and a paroxysm of tachycardia of mixed form follows; the type of tachycardia, at first consisting of beats from foci A, B, and C, ultimately becomes still more complicated, and the coördinate action of the heart may ultimately become submerged and replaced by the condition termed fibrillation. The transition from the first extrasystole to the ultimate condition of fibrillation is a gradual one, a passage from the less to the more complex.[2]

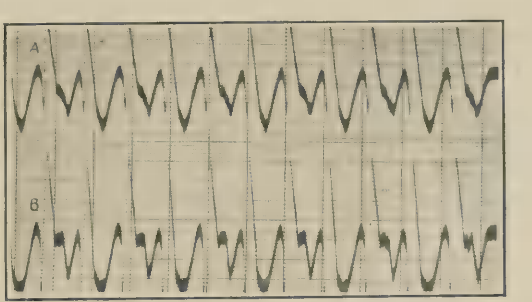
FIG. 1.



Simultaneous electric curves taken directly from two closely adjoining points on the wall of the right ventricle, showing the normal heart beats. The vertical lines represent given instants in time at 1/5 second intervals. Ordinates 1 cm. = 20 millivolts. (Reduced to half size.)

I argue from these and from similar facts that all the disturbances of the heart's action at present under consideration have the same essential pathology, whose simplest expression is the solitary premature contraction. But I would add that this conclusion appeals to me as one open to discussion; it is of no small importance if true, for in that case the key to some of the most important problems of cardiac pathology will be found when the cause of the solitary extrasystole is discovered.

FIG. 2.



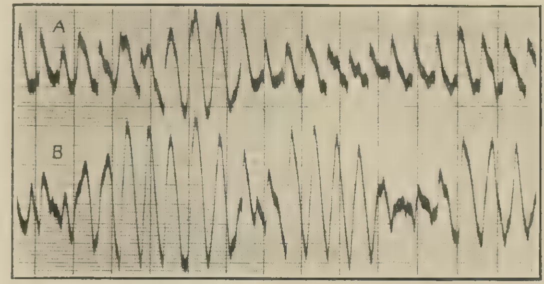
A record from the same points while the apex of the ventricle is stimulated with a weak faradic current. The heart is responding irregularly but coördinately at about 300 per minute. (Reduced to half size.)

That ventricular fibrillation is associated with independent activity of closely adjoining strands of muscle in the wall of the ventricles is, I think, clear by such records as those which I now show you. Suppose we place two small contacts on the superficies of the heart, exposed experimentally, and lead from each of them to an indifferent point.[3] You may obtain with a sensitive galvanometer two simultaneous curves, indicating the electric state of the muscle in these adjoining areas. When the heart is beating normally you record curves from the two areas which are practically identical, the time interval between corresponding deflections in the two curves being so small as to be imperceptible to the naked eye. (Fig. 1.) The two areas become active coördinately. Now if you stimulate a part of the ventricle some distance away with a weak faradic current and gradually increase the strength of this current, eventually the heart responds to it. It responds by a series of somewhat irregular but very rapid contractions at a rate of about 300 per minute. So rapid are the contractions that the circulation is seriously embarrassed; yet the records at this stage still show that the two muscle areas have become active at constant intervals relative to each other; the heart wall is still beating coördinately. (Fig. 2.) But press the stimulation further and the phenomenon known as fibrillation supervenes, and immediately it comes you see its characteristic writing. (Fig. 3.)

---

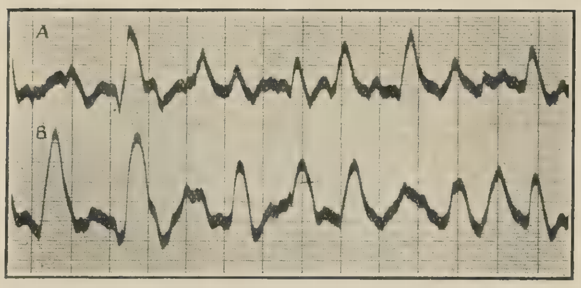
[2] The fact that the transition is sometimes less gradual and that the growth of the disorder is in steps does not affect the general line of reasoning.

FIG. 3.



Immediately after the onset of permanent fibrillation. Coördination between the two areas is now lost. (Reduced to half size.)

FIG. 4.



The same fibrillation at a later stage. (Reduced to half size.)

The deflections are irregular in amplitude and incidence and occur at first at a rate of some 500–600 per minute; no blood is ejected from the heart at this stage; and the records show that the adjoining muscle areas are no longer coördinated. Each gives the same type of curve, but individual deflections do not correspond either in amplitude or time incidence. The heart dies in this state, and as it dies the oscillations become slower and more rounded (Fig. 4), but still maintain their independence in the simultaneously written curves. This observation leaves no doubt of the independent activity of the adjoining muscle areas, and shows that the subdivision of the muscle is considerable. For such curves are obtained when the contacts actually meet each other. That this independence is the result of independent formation of impulses, consequent upon the spread of a condition of irritation, appeals to me most forcibly.

I pass to a consideration of the cause of extrasystoles as they occur in disease, and to the causes of allied disorders, and in doing so am aware that I enter a field of controversy.

RELATION BETWEEN EXTRASYSTOLIC AND PHYSIOLOGICAL BEAT.

I have already drawn attention to the similarity between the reaction of the heart to an electric shock and to its reaction to whatever creates an ordinary extrasystole, and have hinted that the two reactions may have much in common. But the matter may be approached in a more convincing fashion if we closely compare the extrasystole with the physiological beat. My present thesis is that there are clear distinctions between them. These distinctions are to be sought in the nature of the processes which precede and induce contractions and not in the contraction itself.

1. The most remarkable character of the extrasystole is its *prematurity*. It occurs as a rule long before such time as a heart-beat is expected. The process which prepares the physiological heart-beat is slow, that which precedes the extrasystole is abrupt. In the human ventricle, when it is isolated and beating in response to its own natural rhythm, a beat of physiological type is prepared in no shorter time than half a second, usually the time required is as much as a second and a half; the extrasystole may arise in the ventricle after no greater rest than a twentieth or a fiftieth of a second.

2. The second distinctive character which I would emphasise is the absence of rhythmic tendency. Extrasystoles, it is true, may occur in sequence, but that is not their habit; their habit is to stand isolated. The physiological heart-beat is essentially rhythmic; when a beat of this kind is once built up the next is prepared more readily, and the beats occur in an accelerating succession until the final rate is fully established. If the extrasystole is repeated, and such repetition is, as I have stated, not habitual, then this acceleration is not seen,[4] the rate is maximal from the commencement and is maintained as a general rule with wonderful uniformity. But the extrasystole is almost always isolated, and it is followed by a pause which on account of its length offers many opportunities of repetition of which the extrasystole fails to avail itself. The contrast with the natural ventricular beat could not be greater; the latter proclaims itself at each opportunity; when impulses are lacking to stimulate the ventricle, the ventricle initiates its own slow rhythm; if impulses reach it irregularly the ventricle will beat spontaneously at each lapse of a given period of time.

3. Those influences which promote spontaneous rhythms do not necessarily promote premature contractions. In those centres where the property of rhythmic impulse formation is highly developed, this property is always active under conditions of normal nutrition; though it may be temporarily dormant if the centre under observation is already responding to a more active rhythm. It suffices to

---

[3] The lead may be from closely placed paired contacts on the heart wall; the effects are the same.

[4] Such, at all events, is the rule.

inhibit the receipt of such impulses, when the centre invariably awakens. Extrasystolic contractions are not seen in these circumstances; they are especially associated with malnutrition or poisoning. There is no relation between the heightened activity of physiological heart rhythms and the prevalence of extrasystoles. Often influences which depress one favour the occurrence of the other. No more notable example could be cited than the action of potassium chloride, which in full doses retards natural impulse formation in the heart, while it creates extrasystoles.

4. The reaction to the heart nerves is different in the two cases, and this has been noticed particularly in respect of the vagus. Stimulation of the vagus slows the physiological rhythm, be it of auricular or auriculo-ventricular origin; and with graded stimulation the slowing is gradual and is followed by an equally characteristic and gradual acceleration until the original rate is reached or surpassed. The action of the vagus upon extrasystolic beats, occurring successively, is essentially different. There is either no reaction or an abrupt and complete termination of these beats.

5. The naturally rhythmic centres are not the centres from which extrasystoles commonly arise. Electrocardiographic studies have taught us a great deal as to the foci from which contractions spring. Physiological beats are propagated mainly from three centres—the sino-auricular and auriculo-ventricular nodes and the auriculo-ventricular bundle. These are the most rhythmic centres of the heart. The rarest forms of extrasystole are those which arise in these structures; they come as a rule from other regions of the heart.

6. The physiological rhythm is fastest which is propagated from tissue lying nearest to the superior cava, and as we pass to other centres the rhythmic properties are found to be less highly developed. There is no known difference in the rates at which extrasystolic contractions are built up in the auricle and ventricle, whether the rate be judged of in the solitary or in the successive beats.

These arguments will suffice to support the proposition, which I offer for discussion—namely, that certain of the preparatory processes which precede the normal contraction on the one hand, and the extrasystolic contraction on the other are essentially different, and that those which precede the latter are of a kind foreign to the physiological heart.

The Rôle of the Heart Nerves in Causing Extrasystoles.

I turn to the final problem upon which I have remarks to offer: the relation of the heart nerves to extrasystolic contractions. And at the beginning let it be emphasised that this is a distinct problem from the influence of the nervous apparatus upon the activities of natural or physiological impulses, so at all events I think it should be considered. In discussing this question I shall refer more than once to the important recent work of Rothberger and Winterberg. Rothberger and Winterberg's papers must be read with a close regard for the nature of the rhythms which they produce; they have not recognised the possible, nay probably, distinctions between the two types of contraction which we have just reviewed. Many of the examples of new rhythms which they publish as resulting from nerve stimulation are not, or are not certainly, of an extrasystolic nature, but are, or may be, accelerated rhythms of the physiological order, though emanating from abnormal centres. This criticism is a serious though not a complete criticism of their work, and one which not immaterially affects their conclusions. I would also caution you in another respect. We shall discuss the influence of the nerves upon extrasystolic contraction, and use as illustrations successive contractions and fibrillation. This is necessary while the facts at our disposal are relatively meagre; but it should not be forgotten that the argument is based to some extent upon the hypothesis that fibrillation is extrasystolic in kind; in the future it will be necessary to safeguard our conclusions by a distinct consideration of each form of cardiac disorder.

Let us consider Rothberger and Winterberg's results in some detail. In 1911 a paper, which has commanded widespread attention, appeared under their names.[5] On page 353 of this communication stands the conclusion that: "This conjecture obtains in the results of our experiments a far-reaching confirmation. For, despite many exceptions, the combined stimulation of right vagus and left accelerans gives, with unmistakable frequency, left-sided ventricular extrasystoles which interrupt the vagus standstill." As an instance, they cite Fig. 3 as an illustration of this important conclusion. The curves of this figure show perfectly clear events. While the sympathetic is being stimulated, right vagus stimulation produces in the first instance slowing of the whole heart, and as the heart slows the ventricle escapes; rhythmic beats, at a rate slower than the original heart-rate, appear in the curves. These beats in the electrocardiograms have the same outlines as extrasystoles from the left ventricle. Now I have already said that extrasystoles usually arise in abnormal heart foci, and amongst other positions of origin is the ventricle. Arising in the ventricles they produce highly abnormal electrocardiograms which depend upon the direction taken by the excitation wave in the heart. Rothberger and Winterberg have fallen into this error; they have taken the abnormal origin of the beats as an evidence of their extrasystolic nature; but this reasoning is not justified by our knowledge, beats not only of the extrasystolic but also of the physiological order may be associated with the same form of electrocardiogram, for the two forms of heart contraction may come from the same heart focus and the courses of the excitation waves may be the same through the muscle. The conditions of Rothberger and Winterberg's experiments were precisely those which would enhance a physiological rhythm in the ventricle hitherto dormant, and the vagal slowing would permit its appearance. The curves in question are unmistakably examples of an escape of this kind; they contain no evidence of extrasystolic rhythms. And if we look through the figures of this paper we can find, with two possible exceptions, no substantiation of their conclusions. The possible exceptions are two examples of fibrillation of the ventricles stated to be the result of similar nerve stimulations. Now ventricular like auricular fibrillation is a phenomenon which is not of infrequent occurrence in animals under experimental conditions. It is not the first occasion on which one or other disorder is reported to have followed interference with the vagus[6]; the disorder comes in what appears to be a most capricious fashion. It was seen on three occasions in the 30 experiments upon which their paper is based. I put it to you that if there was evidence of extrasystolic beats—allowing that fibrillation is of this nature—on only three occasions in 30 experiments confined to interference with the heart nerves, then we must inevitably conclude that the vagal stimulation, so often repeated without success, was no more than one, and probably by no means the chief causative factor. If we are to conclude that nervous impulses, acting alone, are capable of producing extrasystolic beats, we require far stronger evidence than this. An experiment must be devised in which by such interference the result is invariable or almost invariable; and evidence of this kind is necessary, for we now know the causes of extrasystole are of a most elusive kind, and creep into experiments unseen and unheeded. The isolated examples of fibrillation in Rothberger and Winterberg's experiments are to be ascribed largely, if not entirely, I think, to such factors.

---

[5] Pflüger's Archiv, 1911, cxli., 343.

[6] It is an unfortunate fact that the two curves published as examples by Rothberger and Winterberg are almost the only ones of their series in which the automatic signal of vagus stimulation is lacking.

We pass finally to a discussion of observations of a somewhat different kind. I refer to the later papers of Rothberger and Winterberg and to those of Levy.[7] The former writers have shown that stimulation of the sympathetic nerves is followed by beats of an extrasystolic nature when the heart has been previously poisoned by barium chloride. Levy has shown that sympathetic stimulation is followed by the appearance of beats of the same kind, or by their increased formation, when the heart is poisoned with small doses of chloroform. The evidence for both these statements is, I think, conclusive.[8]

It has to be acknowledged that the nerves of the heart may play a very significant rôle in producing the disorders of mechanism considered. Can we define this rôle more distinctly? There are, so it seems to me, two questions to which answers may be returned at the present time. Has it been shown that abnormal nerve impulses playing upon a normal heart may be responsible for extrasystoles or the higher types of disorders? To this question we may return a negative answer. May nervous impulses playing upon a supersensitive or irritable organ provoke these curious contractions? To this question we may return an answer in the affirmative.

It is a striking fact that both in the experiments of Rothberger and Winterberg with barium chloride, and in those of Levy with chloroform, before the sympathetic is stimulated, conditions predisposing to extrasystole are known to be affecting the heart. Given such conditions, the sympathetic influences enhance the pre-existing tendency, and the disturbance or an exaggerated disturbance follows. So far, and no further, are we warranted in carrying our conclusions to-day.

---

[7] Rothberger and Winterberg: Zentralblatt für Physiologie, Band xxv.; also Pflüger's Archiv, 1911, cxlii., 46; Levy and Lewis: Heart, 1911-12, iii., 99; Levy: Heart, 1912-13, iv., 319; and 1913-14, v., 299.

[8] Many of Rothberger and Winterberg's curves are open to the objections raised in criticisms of the earlier paper, but in some of their published figures the new beats have all the features of extrasystoles, and must, I think, be accepted as such.

OXFORD OPHTHALMOLOGICAL CONGRESS.—Mr. Sydney Stephenson has been elected master of the Congress, vice Mr. R. W. Doyne, nominated as past-master. Mr. P. E. H. Adams (Oxford) has become deputy master, and Mr. A. Bernard Cridland (Wolverhampton) honorary secretary. Colonel R. H. Elliot, I M S, has been elected a member of the council.

OBSERVATIONS UPON 31,000 CONSECUTIVE MEDICAL EXAMINATIONS,

CONDUCTED CHIEFLY FOR THE PUBLIC SERVICE.

BY SIR JOHN COLLIE, M.D. ABERD., J.P.,
MEDICAL EXAMINER FOR THE LONDON COUNTY COUNCIL; CHIEF MEDICAL OFFICER FOR THE METROPOLITAN WATER BOARD.

THE following observations are based upon 31,000 consecutive medical examinations made on behalf of two large public bodies and various insurance companies and solicitors during the last nine years. The figures are arranged in the following groups:—

	Cases.	Examinations.
I. Entrance examinations as to physical fitness	12,189 ...	13,526
II. Accidents amongst employees	3,667 ...	6,858
III. Sickness amongst employees	3,499 ...	7,391
IV. Medico-legal cases	2,216 ...	3,396
	21,571	31,171

I.—*Entrance Examinations as to Physical Fitness.*

Results of Medical Examination as to Physical Fitness of Candidates for Entrance into the Public Service.

Passed at first examination	9694	
Passed after postponement	990	
Passed temporarily, subject to re-examination yet to take place	82—	10,766
Rejected at first examination, one disability only...	1037	
Rejected at first examination, more than one disability	149	
Rejected after postponement...	237—	1,423
(Representing 13,526 examinations.)		12,189

Proportion of rejections.—A comparison of the figures contained in this table with those presented in 1911 will show that the proportion of candidates for the public service I have had to reject has considerably increased. Up to 1911 the percentage of rejections was 9·9 per cent., but in the past three years I have found it necessary to refuse 14·4 per cent. A large part of this increase is due to the number rejected on the ground of dental caries. It seems incredible that such a large number of people are ready to forfeit their chance of employment rather than undergo the treatment necessary to put their mouths into a proper condition.

Summary of Causes of Rejection of 1423 cases.

Defective visual acuity	479	Hydrocele	8
Dental caries	254	Refused physical examination	7
Heart disease	110	Obesity	6
Albumin	109	Goitre	6
Colour blind	103	Hæmorrhoids	5
Hernia	82	Anæmia	5
Varicose veins	54	Alcohol	4
Disease of lungs	25	Gonorrhœa	4
Poor physique	22	Mentally defective	4
Syphilis	18	Tubercular spine	3
Various skin diseases	16	Deformity	3
Diabetes	13	Urethritis	3
Varicocele	11	Fainted at vaccination	3
Debility	10	Various conditions of infrequent incidence	48
Deafness	8		

Varying standards.—The relative proportions of most of the defects which have led to rejection are very fairly maintained. Some of the variations may be accounted for by the differing standards of tests which have to be applied, having regard to the diverse natures of the employments proposed. Thus drivers of tramcars and fireman must have perfect vision, but there is no reason why those seeking employment in a clerical capacity should not be passed, even though possessing defective vision, provided suitable corrective lenses are procured.

Desirability of medical examination prior to employment.—Having regard to the large percentage of rejections I think I am justified in again urging the desirability of instituting a system of medical examination prior to employment. I do not advocate the employment of only those who are physically perfect (the army of unemployed would be of enormous dimensions if that standard came into operation), but I feel that in dealing with subsequent injuries or illnesses the advantage to be derived from a knowledge of pre-existing defects would be enormous, and, in addition, many men would not be permitted to undertake work the performance of which would be inviting disaster to themselves and others in their particular physical condition. Men with heart disease are often employed to perform heavy work because of their apparently robust condition, but a medical examination would disclose their total unfitness for anything of the kind. The big rise in the number rejected on account of poor physique from 4 to 22 need cause no alarm as being evidence of physical deterioration in the race, because in such a body as the Fire Brigade a very high standard of physique is demanded.

Examination of urine. (*a*) *Sugar.*—I have confirmed by further observation the opinion I expressed in 1911, that the indications of glycosuria (high specific gravity and crystals of glucosazone) so often found upon a first examination of urine are frequently merely temporary, and are the result of the mental anxiety and physical stress which so many candidates experience when appearing before the committee of a public authority and undergoing a medical examination with a view to securing an appointment. Although glycosuric urine is often indicative of the early stage of true diabetes, and the urine in these cases may respond to all the tests demonstrating diabetes, I believe the condition may well be of a temporary character and should not necessarily lead to rejection. Even if the diabetic condition is undoubted, the nature of the employment proposed may justify a pass. I remember the case of a professional man, aged 58, who had diabetes, but as his services were only required for some eight or ten years I ventured to take the risk, and after stating the facts quite frankly to his future employer advised his acceptance. He duly served his time, and died two years after leaving the service.

(*b*) *Albumin.*—The examination of considerably over 5000 further specimens of urine strengthens my opinion that we have not by any means reached the limit of the knowledge to be obtained by this procedure. No candidates for the public or any service should be refused admission merely because a first examination of the urine discloses the presence of albumin. Even if albumin is persistently present (it is frequently only temporarily so) it is not fair, especially to young candidates, finally to reject them until the centrifugalised deposit has been microscopically examined. In a large number of cases a second specimen of urine, although passed but a few minutes after the first, will show no trace of albumin, the probability being that the first reaction was produced by nuclear albumin obtained from a deposit lying in the urethra, the result, may be, of an old gleet.

Physiological or adolescent albuminuria certainly does not point to organic change in the kidneys. In the vast majority of specimens of urine passed by people under 22 or 23 years of age the presence of albumin will be found to be a temporary condition. My friend, Sir James Goodhart, tells me that he finds that when albuminuria is merely functional cold acetic acid when added to the urine causes it to assume a cloudy opalescent appearance. He adds: "I am sure this is a really valuable constructive test, for this is hardly ever found with nephritic albumin." In order to determine whether the albuminuria is or is not due to definite nephritic mischief the deposit should be subjected to microscopic examination at stated intervals on several consecutive days. Hyaline casts alone do not indicate disease.

Dental caries.—During the past three years I have paid special attention to the question of pyorrhœa alveolaris and the absence of healthy teeth. Many of the septic conditions—e.g., rheumatoid arthritis, rheumatism—the origin of which until recently has been sought in vain, will be found to be due to the slow, chronic poisoning brought about by the condition in which the working classes keep their teeth. A comparatively slight degree of traumatism is increased, and the period of convalescence unduly prolonged by the presence of oral sepsis; on several occasions the removal of decayed teeth during the period of disablement following an accident has facilitated recovery. I think, therefore, that when examining for admission into the public service special care should be taken that the teeth of a candidate are in good condition, so that he may not only digest his food and maintain his health, but that in the event of an accident recovery may not be delayed by the impetus traumatism seems to give to general septic absorption from pyorrhœa alveolaris. I have been much struck by the unwillingness of candidates to have decayed teeth extracted, and find that the shorter the period allowed them for extraction the more likely are they to have extractions performed. I now make it a condition of acceptance into the service that the mouth shall be in a healthy condition.

II. AND III.—*Examination of Employees for Accidents and Sickness.*

In my former report I stated that employees who have been on the sick list for 28 days from any cause are sent to me for examination and report, and that this was found to be a considerable check upon the temptation to malinger or unduly to prolong illness after accidents or sickness. Further, I pointed out that the 28-day rule, though by no means equal to systematic re-examination at set intervals, certainly enables me to keep an eye to some extent generally upon the health of the staff. For instance, a tramway driver was discovered to be suffering from aortic regurgitation and a school attendance officer from locomotor ataxia when they presented themselves on the expiration of 28 days' sick leave on account of a slight injury in the first case and a sprained ankle in the second. Recently this rule has been modified in certain sections of my work, accident cases being submitted as soon as practicable after their occurrence, without waiting for 28 days to expire.

Results of Examination of Employees as Regards Fitness for Work.

	Total accident and sickness cases. (7166).	Accident cases only. (3667).	Sickness cases only. (3499).
1. Cases certified fit for duty on first examination	20·2% ...	23·3% ...	17·7%
2. Cases requiring further leave from the date of the first examination ...	60·8% ...	64·4% ...	55·8%
3. Cases permanently unfit after single or final examination; also including deaths immediately under my notice...	13·3% ...	4·3% ...	23·9%
4. Undoubted malingerers	5·5% ...	8·0% ...	2·6%

Classification of 3667 Cases of Accidents. (Representing 6858 examinations.)

Contusions of limbs	748	= 20·4	per cent.
Wounds (various) of limbs	617	= 16·8	,,
Fractures of bones	341	= 9·3	,,
Sprains of limbs	281	= 7·7	,,
Herniæ	231	= 6·3	,,
Back, injuries of	216	= 5·9	,,
Head injuries and traumatic neurasthenia	204	= 5·6	,,
Injuries to the eye	190	= 5·2	,,
Synovitis of knee	124	= 3·4	,,
Burns	85	= 2·3	,,
Injuries of chest and neck	57	= 1·6	,,
Injuries of abdomen, pelvis, and organs of generation	46	= 1·2	,,
Dislocations of limbs	46	= 1·2	,,
Amputation of fingers for traumatism	32	= 0·9	,,
Displaced semilunar cartilage of knee	30	= 0·8	,,
Injuries of ear and mouth	22	= 0·6	,,
Unclassified	104	= 2·8	,,
Undoubted malingerers	293	= 8·0	,,

There is still a tendency to make the happening of a slight injury the pretext for obtaining the utmost amount of compensation. It is obvious that, if my experience is not singular, a state of things is arising that calls for careful attention.

Classification of 3499 Cases of Sickness, showing Proportion of Certain Diseases of More Frequent Incidence. (Representing 7391 examinations.)

Infective Diseases, 968 cases = 27·7 per cent.	
Pulmonary and laryngeal tuberculosis	230
Influenza	170
Rheumatism	170
Pneumonia	95
Rheumatic fever	72
Enteric fever	53
Primary syphilis (secondary syphilitic conditions are classified under systems particularly affected)	31
Rheumatoid arthritis	21
Tonsillitis	18
Empyema	15
Rheumatic gout	15
Scarlet fever	15
Diphtheria	14
Pulmonary tuberculosis suspected	11
Laryngitis, non-tubercular	6
Mumps	5
Actinomycosis	1
Various conditions of infrequent incidence	26
Diseases of the Nervous System, 602 cases = 17·2 per cent.	
Neurasthenia	221
Insanity and mental depression	83
Sciatica	53
General paralysis of the insane and locomotor ataxia	51
Cerebral hæmorrhage	37
Epilepsy	36
General mental deterioration	13
Disseminated sclerosis	10
Paralysis agitans	7
Heatstroke and sunstroke (not accident under the Workmen's Compensation Act)	7
Writer's cramp	6
Various conditions of infrequent incidence	78
Diseases of the Digestive System, 341 cases = 9·8 per cent.	
Gastric conditions	106
Appendicitis	63
Diseases of the rectum	42
Hæmorrhoids	39
Diseases of the liver	32
Duodenal ulcer	18
Abscess of jaw	5
Various conditions of infrequent incidence	36
Diseases of the Circulatory System, 255 cases = 7·3 per cent.	
Valvular disease of the heart	136
Varicose veins and ulcers, thrombosis and phlebitis	93
Fainting on duty	11
Arterio-sclerosis	4
Various conditions of infrequent incidence	11
General Diseases, 243 cases = 7·0 per cent.	
Debility	71
Premature senility	61
Anæmia	42
Gout	35
Obesity	9
Boils	7
Various conditions of infrequent incidence	18
Diseases of the Respiratory System, 236 cases = 6·8 per cent.	
Bronchitis and bronchial catarrh	125
Pleurisy	47
Asthma	45
Various conditions of infrequent incidence	19
Diseases of the Organs of Locomotion, 119 cases = 3·4 per cent.	
Lumbago	38
Ulcers of leg and foot	20
Bursitis	7
Bunion	6
Tubercular synovitis of knee	3
Tubercular abscess of foot	1
Various conditions of infrequent incidence	44
Diseases of the Urinary System, 106 cases = 3·0 per cent.	
Nephritis	61
Diabetes	17
Stone in kidney or bladder	12
Cystitis	4
Various conditions of infrequent incidence	12
Diseases of the Eye, 105 cases = 3·0 per cent.	
Defective vision (various causes)	36
Conjunctivitis	13
Iritis	11
Cataract	10
Choroiditis	6
Ophthalmia	4
Glaucoma	3
Various conditions of infrequent incidence	22
Diseases of the Skin, 101 cases = 2·9 per cent.	
Eczema	28
Sycosis	11
Erysipelas	9
Ringworm	8
Various conditions of infrequent incidence	45
Morbid Conditions Incident to Various Parts, 92 cases = 2·6 per cent.	
Cancer	62
Various conditions of infrequent incidence	30
Toxæmias, 80 cases = 2·0 per cent.	
Alcoholism	75
Various conditions of infrequent incidence	5
Diseases of the Generative System, male and female, 64 cases = 1·8 per cent. (18 of these cases venereal.)	
Diseases of the Ear, 40 cases = 1·2 per cent.	
Deafness due to various causes	16
Middle-ear suppuration	8
Mastoid abscess	5
Various conditions of infrequent incidence	11
Diseases of the Lymphatic System, 37 cases = 1·1 per cent.	
Tubercular glands	11
Inflamed glands, not tubercular	10
Myxœdema	1
Various conditions of infrequent incidence	15
Diseases of the Nose, 19 cases = 0·6 per cent.	
Undoubted malingerers, 91 cases = 2·6 per cent.	

Alcoholism.—I should like specially to refer to the cases of alcoholism, many of which are frequently submitted to me for report. In these cases the temptation is to consider the service and ignore the individual. During the past nine years there have been many cases of undoubted alcoholism; none of these have been dismissed peremptorily. I have taken a special interest in each case, and tried to gain the confidence of and assist those who have promised to coöperate with me in helping them to abstain totally from alcohol. In many instances I have been able to bring about total abstinence and restore self-respect. It is difficult to be accurate in dealing with this question; failure is so common, and deceit and falsehood (the consequences of a depraved mental condition) are almost invariably present. Close touch with the heads of departments has, however, afforded me special facilities. The following are the results to date of 43 consecutive cases coming under my care since 1908:—

No relapse. Quite satisfactory. Total abstainer one year or over	15
Total abstainer under one year	5
Relapsed and recovered. Moderately satisfactory. Either total abstainer for a period under 12 months from relapse, or only semi-abstainer	9
Relapsed. Unsatisfactory. Died or lost sight of	14

As statistics go, I think it will be found that these are unusually satisfactory results, which may perhaps be explained by the fact that the men concerned are fully cognisant that their irregularity has been reported to me as medical examiner, and that practically I have the final say as to their retention in the service. Hitherto in every case I have taken full advantage of my somewhat autocratic position, and I find it of much assistance in compelling the exercise of that will power which is so essential to recovery from this disease, but which, from the nature of the complaint, is so difficult to bring into operation. A judicious exhibition, often even a parade of despotic authority, combined with a personal and sympathetic interest (in most cases entailing frequent unofficial interviews), has brought about results which are the best, I believe, that have been published. They are so gratifying that they may well be an incentive to others similarly placed.

Venereal disease and its sequelæ.—Much attention is at present being paid to the subject of venereal disease, and some interest may be found in the following particulars of the cases which have come under my observation:—

A. In the 12,189 entrance cases—

Primary syphilis	23	cases.
Gonorrhœa	5	,,
Urethritis	4	,,
Locomotor ataxia	1	,,
Urethral chancre	1	,,
Syphilitic iritis	1	,,
Gleet	1	,,
	36	(= 0·29%).

B. Amongst the 3667 accident cases there were 2 cases of locomotor ataxia accelerated by traumatism. There was also 1 case of gonorrhœa.

C. In the 3499 cases of sickness:—

Primary syphilis	31	cases.
Gonorrhœa (including orchitis, cystitis, urethritis, and epididymitis)	19	,,
Definite specific history in the following:—		
Arterio-sclerosis, syphilitic	4	cases.
Aneurysm ,,	9	,,
Glossitis ,,	1	,,
Cataract ,,	1	,,
Choroiditis ,,	2	,,
Ptosis ,,	1	,,
Laryngitis ,,	3	,,
Progressive muscular atrophy, syphilitic	1	,,
Tonsillitis, syphilitic	1	,,
Disease of ankle, syphilitic	1	,,
Ulcer of ankle ,,	2	,,
Gumma of thigh ,,	2	,,
Ulcer of knee ,,	1	,,
Synovitis of knee ,,	1	,,
Locomotor ataxia and general paralysis of the insane	51	,,
Gumma of brain, syphilitic	2	,,
Mental aberration ,,	1	,,
Skin disease ,,	3	,,
Paralysis due to syphilis (Also 1 case doubtful syphilitic.)	1	,,
Cerebral hæmorrhage, syphilitic (Out of a total of 29 cases.)	8	,,
Epilepsy, syphilitic (Also 8 cases doubtful syphilitic, out of a total of 36 cases.)	7	,,
Chorea (one case doubtful syphilitic)	—	
Iritis, syphilitic (Also 4 cases doubtful syphilitic, out of a total of 11.)	2	,,
Disseminated sclerosis, syphilitic (Also 1 case doubtful syphilitic out of a total of 10.)	1	,,
	156	(= 4·4%).

D. Of the 2216 medico-legal cases there was definite indication of venereal disease in 19 cases, and strong suspicion of it in at least 6 others.

IV.—*Medico-legal Cases.*

An analysis of the 2216 medico-legal cases in view of their special character would serve no very useful purpose, so I content myself by remarking that I have not discovered anything in them to vitiate any of the deductions I have drawn from my other examinations.

Porchester-terrace, W.

ON A METHOD OF MAKING CULTIVATION MEDIA WITHOUT PREPARED PEPTONES, AND ON A PEPTONE-FREE MEDIUM FOR GROWING TUBERCLE BACILLI.

BY S. R. DOUGLAS, M.R.C.S. ENG., L.R.C.P. LOND.,
CAPTAIN I.M.S. (RETIRED); ASSISTANT DIRECTOR, INOCULATION DEPARTMENT, ST. MARY'S HOSPITAL, PADDINGTON.

IN the past, owing to the ease with which various chemical products could be obtained, bacteriologists have been satisfied to follow blindly a ritual of media-making. With the outbreak of the war, however, the supply of one important ingredient, Witte's peptone, almost universally used in this ritual, was suddenly cut off, and it became imperative—especially in this laboratory, where very large quantities of culture media are being used for the preparation of vaccines for our Army and Navy, and also for the French Army—to look forward and prepare for the time when Witte's peptone was no longer available. The preparation of media without the addition of prepared peptones has had to be provided for in the past; for instance, Haffkine was faced by a similar problem when he undertook to make plague vaccine for the natives of India. Since peptone, being derived from pigs, is abhorrent to a Mohammedan, and the use of beef in any form equally so to a Hindu, Haffkine overcame both these difficulties by autoclaving goat's flesh with hydrochloric acid, and obtained a satisfactory medium.

The method of media-making described below gives constantly a very efficient medium, and has proved in my hands more simple and easier than Haffkine's method. Fresh bullocks' hearts having been obtained, the fat and large vessels are removed. The meat is then finely minced, and to the mince thus obtained from an average-sized heart four litres of water are added. This mixture, after being thoroughly stirred and rendered faintly alkaline to litmus, is heated to between 70° and 80° C. After cooling to 45° C. 1 per cent. of trypsin solution (40 c.c. to the four litres) is added, the preparation of trypsin used being Allen and Hanbury's liquor trypsin co. This, in view of the fact that the preliminary heating has destroyed the antitryptic power of the meat juices, rapidly breaks down some of the albumins present. The trypsin is allowed to act for from two to three hours, the temperature being kept raised by placing the vessel containing the mixture in an incubator at 37° C. The next process is to precipitate the unaltered albumins and to render the broth easily filtrable, and with this in view the mixture is rendered slightly acid with acetic acid and brought to the boil. The coagulated proteids and other solid matters can now be almost entirely separated by straining through a bag of close-meshed muslin.

After rendering the fluid thus obtained alkaline to litmus, a small quantity of calcium chloride (about 0·5 grm. to the 4 litres) and 0·25 per cent. of sodium chloride are added, and the resulting broth is then autoclaved for an hour at 115° C. so as to precipitate thoroughly any phosphates that may be in solution, filtered through filter paper, and then tubed and sterilised as in the case of ordinary peptone broth. In making agar the agar powder is best added before the phosphates are precipitated, as the prolonged heating brings the agar thoroughly into solution.

This medium has the following advantages over that made from beef extracts and prepared peptones:—1. The cost is very much less. 2. The growth of the bacteria both on the solid and liquid forms has proved to be very much more abundant than that obtained on the media usually employed; for instance, it has been found that four times more typhoid bacilli were obtained from agar bottles in a given time containing medium thus made than in the case of medium made from beef extract and Witte's peptone.

A possible explanation of the almost phenomenal growths obtained on this medium is that, in addition to peptones and albumoses, of which Witte's peptone is composed, it contains products, such as the amido-acids, which represent a further breaking down of the albuminous molecule, products which are very likely to be easily assimilated by bacteria and built up again by them into their distinctive protoplasm. The only disadvantage of the medium is the longer time and greater trouble that have to be taken in its preparation.

A Peptone-free Medium for the Cultivation of the Tubercle Bacillus.

The medium, the preparation of which is described below, was the outcome of the following observations. In the first place, it was noticed in cultivating tubercle bacilli on glycerine potato, that frequently an abundant growth of the tubercle bacillus occurred on the surface of the glycerinated salt solution which was contained in the lower part of the tube. Attempts were therefore made to make a broth from potatoes which would give a good growth of such bacilli. On such a broth good growths were frequently obtained, but from time to time an individual brew gave but unsatisfactory results. These unsatisfactory results seemed to rest with some quality of the potatoes rather than with any variation of alkalinity, &c. Noting, however, that the tubercle bacillus seemed readily to assimilate even coagulated albumin, it was determined to try the effect of adding some form of soluble albumin, unaffected by the temperature necessary for the sterilisation of the broth, and with this in view various casein preparations on the market, sold under patent names, were tried in order to ascertain if these, when added to the extract of potatoes, would ensure a medium giving constant and abundant growth of the tubercle bacilli. The preparation giving the most satisfactory results was that sold under the name of "Plasmon."

The medium is made in the following manner. Potatoes are skinned, then passed through a mincing machine, and the resulting pulp is weighed. To each pound one litre of water is added and allowed to extract over night at room temperature. The solid matter is now removed by straining through muslin, and the resulting fluid is heated in the autoclave to 115° C. A sufficient quantity of acetic acid to render the hot fluid faintly acid is next added, which causes the suspended matter, starches, albumins, &c., to agglutinate into large masses, rendering the passage of the fluid through filter paper rapid and easy. The fluid thus obtained is rendered faintly alkaline to litmus, and 0·25 per cent. of glucose, 5 per cent. of glycerine, and 200 cubic centimetres per litre of a 2 per cent. slightly alkaline solution of plasmon are added. On the addition of a white of an egg to each litre a further heating to 100° C. clears the fluid, and on filtration gives a clear brown-coloured broth, which is then distributed in flasks and sterilised by steaming for 30 minutes on three successive days. Agar medium can also be made from this broth, which gives an abundant growth of human tubercle bacilli having but very slight adherence to the agar surface, and in consequence easily lifted off with a coiled platinum wire, and floated on to the surface of broth when it is desirable to grow the organism on fluid media.

THE TRANSPORT OF THE WOUNDED IN WAR.[1]

BY EMM. KONDOLEON, M.D.,
CAPTAIN OF THE RESERVE (ARMY MEDICAL DEPARTMENT); SURGEON TO THE MUNICIPAL HOSPITAL IN ATHENS.

BEFORE dealing with my chief subject I will shortly allude to two special points influencing the surgery during the campaign under consideration.

Shrapnel Wounds.—Indications for Amputation.

The first point concerns the numerous wounds inflicted by shrapnel, which I had the opportunity of observing at Strumnitza in the beginning of the second Balkan war. Near this town an engagement took place about the end of June, 1913, between our infantry and the Bulgarian artillery, which had been accidentally isolated. Almost all the wounds of our soldiers were caused by shrapnel, so that of 200 wounded, who were removed to the hospital of Strumnitza, only two had been wounded by infantry rifle fire and there happened at this time to be no other wounded. Such a concentration of patients wounded only by shrapnel therefore gave us an exceptional opportunity of paying special attention to this sort of injury. Their serious nature, as compared with the wounds inflicted by the bullets of the infantry, is generally recognised. We have observed the severe injuries of the soft parts, the numerous metallic fragments in the brain, and the comminution of the long bones. Infection often complicates this sort of wound.

Dangerous infection is, as a rule, coincident with severe injuries, in which case energetic measures should be taken, but great attention should also be paid to the ordinary discharge of pus from a shrapnel wound, because it often ends in cellulitis. We can take as typical the cellulitis which occurs in consequence of a penetrating wound of the soft tissues. We might be able to prevent this complication if we could deal adequately with the originating cause, which in our opinion is the fact that no distinction whatever is made in military surgery between the dressings for the wounds caused by infantry bullets and those caused by shrapnel. The first we dress by applying tincture of iodine, and the second in the same way. This dressing may practically be suitable for the small infantry bullet wounds, but a shrapnel wound, which is usually infected from the very beginning, has always in its course small gaps surrounded by dead tissues. It is obvious that shaving, cleaning, and the use of tincture of iodine are not sufficient to prevent possible complications under such conditions. Whenever we notice any discharge of pus from the openings we must make adequate incisions and drain the wound. The realisation of this distinction in the dressing of infantry bullet wounds and shrapnel wounds is, no doubt, difficult when many wounded are brought simultaneously and the temporary shelters are very crowded. Under these circumstances we can only divide the wounds into severe injuries, which require much time and care in treatment, and slight cases, which are removed elsewhere as soon as possible. In every other instance this distinction is, I think, practical and necessary, as it prevents serious complications from arising in wounds apparently slight.

---

[1] An address delivered before the Medical Society of Athens.

The second point, which I wish also to deal with briefly, concerns the indication for amputation in the surgical stations which are working near the line of action. Modern surgery aims at being conservative, but I fear that the exaggeration of this tendency is not profitable to the wounded, whose chief desire is that their lives may be saved. I am referring to those cases in which a wounded limb cannot be preserved and the life of the patient is in immediate danger from the progress of sepsis. We all recognise the necessity of amputation in such conditions, and yet we often hesitate, either postponing the operation or sending the wounded to the next surgical station, thereby losing the best moment for the operation, which can be performed anywhere and by any medical man, even though he may not claim to be a surgical specialist. If this view of early operation be generally accepted we shall no longer see wounded men arriving from other stations at too late a stage for amputation because of the fatal progress of sepsis, which excludes any hope for a successful performance of the operation.

Transport of Wounded: Injuries of Spinal Cord and of Skull.

I now come to my chief subject, how to transport the wounded from the temporary stations to the permanent surgical hospitals, the latter being usually situated in large towns. The importance of this subject becomes obvious when one considers the numerous difficulties connected with it. Of course, I do not mean to criticise the methods of the army medical department, my intention being merely to deal with the subject of transport from a purely scientific point of view; neither do I propose to speak of transport from the first line of action—through the ambulance—to the temporary hospitals, as this transport is not amenable to fixed rules, but is carried out in any possible way near at hand. But when the transport must be continued from the temporary stations to the permanent hospitals in the towns there is certainly a need for a more definite system.

First, I have to mention the cases which require immediate surgical intervention. Wounded men belonging to this category are often removed without being operated upon. But all urgent cases must be operated upon in the temporary hospitals, even under unfavourable conditions. The fact of many operations being performed with successful results under canvas proves the possibility of the extension of this measure. With regard to the wounded who do not require immediate operative treatment, such as those having fracture of the spine, with injury of the spinal cord, and consequent paraplegia, we think that they should be the first to be removed. Not one of such patients, as far as I could see, sustained any shock during removal, though it was sometimes carried out under lamentable conditions.

There are two reasons in support of the view that these wounded should be removed first; one is that they are not subject to shock, being in a condition similar to that seen in dogs whose spinal cord has been cut across, for these "spinal dogs" show great resistance to shock. If we observe a wounded man during conveyance over a great distance, presuming that he has a high fracture of the spine with complete paraplegia, we shall be impressed by his regular pulse-rate, quiet expression, and good general condition, while the contrary is observed in severe injuries of the abdomen or the limbs. This resistance to shock on the part of men wounded in the spine enables them to be removed without any further delay. The second reason for immediate transport is clear, for the health of these patients is soon broken, bedsores very often appear, infection of the bladder from frequently passing the catheter is inevitable, and if they remain in the temporary hospitals their condition becomes miserable, whereas if they had been removed at the very beginning to the central hospitals in the towns they would be placed under better treatment.

The removal of those who have penetrating wounds of the skull presents more difficulties. Those who are still under the influence of shock must, of course, be kept on the spot until their condition improves sufficiently to permit further transport. Those who have foreign bodies in the brain, with symptoms of pressure, must be immediately operated upon in the temporary station. Mere enlargement of the existing opening will often be all that is required for the removal of splinters and the relief of pressure. There is no reason for making a systematic search for a bullet lodged in the brain. Patients who require to be trephined would better be previously removed to the permanent hospitals, because if they are operated upon in the temporary station their subsequent removal would be very dangerous in the event of the place having to be evacuated.

Wounds of Thorax and Abdomen; Fractures of Extremities.

There still remain the cases which do not require any intervention, and among them those which are considered to be the most serious should be the last to be removed. As regards penetrating wounds of the thorax, I formed the impression that too much apprehension on our part rendered their transport much slower than was really necessary. In a great number of such cases the wounded were transported from the line of action to the next stations in a quite primitive way, without any bad consequence. In saying this I do not suggest that the prophylactic measures of the first few days may be omitted, but I think that men wounded in the thorax may be removed after a few days' rest. Persistent hæmoptysis, which makes possible a more severe hæmorrhage, is regarded as a contraindication, but I do not think that blood-stained sputum is a contra-indication in itself. It should also be considered that the general condition of these patients is very favourable—when no such complication as hæmothorax or empyema appears—so that they themselves insist upon being immediately transported to the towns. For penetrating wounds of the abdomen the regulation precautions are necessary. Men thus wounded must not be removed before the lapse of a week from the day of injury. We often notice as a result of the confusion prevailing in the use of the term "penetrating" that many superficial wounds of the abdominal walls are registered as penetrating. The distinction between these two categories is easy, requiring only a careful examination. When in really penetrating wounds there is no sign of peritonitis after the first week the patients can be removed without danger. In about ten days we can also remove some slight cases of localised peritonitis, provided there are proper vehicles. Two of these cases have been transported from Cresna to Salonica without further complication.

The transport of patients suffering from complicated fractures of the extremities presents many difficulties, especially when the wounds are infected. In aseptic cases immobilisation with plaster bandages which have openings corresponding to the wound is convenient, but in infected cases with abundant discharge of pus requiring frequent dressing the plaster cannot be used, because it quickly becomes foul and has to be taken off in the subsequent stations, thereby impeding the whole sanitary service. Immobilisation with the ordinary wire leg support is always imperfect, and when possible the plaster must be preferred to it. In extraordinary circumstances, where there is no special material for the dressing of fractures, improvised immobilisation, the methods for which must be taught systematically in time of peace, becomes necessary.

Omitting the slight wounds, we may propose the following order as a general scheme of transport: Fractures of the spine must be removed first, fractures of the extremities in the second place, fractures of the skull in the third place, wounds of the thorax fourth, and penetrating wounds of the abdomen last of all.

Means of Transport.

An important question in connexion with transport has reference to the means by which it is best carried out. For the transport of wounded men from the temporary stations to the central hospitals travelling by railway is often possible, in addition to which we have bearers, motor-cars, ordinary carts, bullock carts, horses and mules, and the sanitary service wagons. A certain number of patients will be able to walk. Transport by bearers recruited locally would undoubtedly be the best of all, if it could be carried out everywhere and on a large scale. It is very comfortable for the wounded, who can rest quietly, even when being conveyed a long way, but unfortunately only a small number of wounded can be transported in this manner. It is therefore good to reserve this transport for the severest cases, in which an unsteady movement of any kind may prove fatal. Next come the motor-cars, which are the best means of transport where there are carriage roads, because they secure both a quick and safe transport, although with some of them the occupants have to endure severe jolting. One of the ordinary transport motor-cars can easily hold 10 wounded persons, so that if 20 or 30 such motor-cars are at our disposal we can have 200 or 300 wounded conveyed every day to a great distance. We made use of these transport motor-cars from Cresna to Salonica, and it proved quite a success. For purposes of transport ordinary horse carts and bullock carts must be replaced by motor-cars where possible. Transport by mules is useful in mountainous regions and when the immediate evacuation of a station becomes urgent. The ordinary transport carriages of the sanitary service are, as a rule, uncomfortable and a cause of shock. It would be desirable if they could be replaced by transport motor-cars.

Athens.

A CASE OF ACUTE EXOPHTHALMIC GOITRE SIMULATING ACUTE OBSTRUCTION.

By G. McCALL SMITH, M.B., CH.B. EDIN., F.R.C.S. EDIN.

THAT quite a number of diseases run such an atypical course that their diagnosis presents the very greatest difficulty is only too well known. Fortunately in many cases, as far as the treatment is concerned, the correct diagnosis is of little moment, but occasionally the reverse of this is the case. Many of us have been faced with the difficulty of diagnosing the gastric crises of early tabes from a ruptured gastric ulcer. Every student is well warned of this pitfall, and rightly. That exophthalmic goitre may closely simulate acute intestinal obstruction is not so well known, however.

To diagnose a case as exophthalmic goitre in which there is no exophthalmos and no goitre seems hardly correct. A more correct designation would be "thyrotoxicosis" or "hyperthyroidism." To the latter the objection may be taken that the name implies a definite knowledge of the pathology of the condition which, in spite of great advances, we do not possess. The name pseudo-exophthalmic goitre is obviously objectionable. The pathology of the glandular condition in true exophthalmic goitre is an increase of the functioning part of the gland. That the toxic symptoms are due to the absorption of this excessive secretion is also probably correct, although absolute proof is still lacking of this. The following case explains the heading of this article.

The patient was a domestic servant aged 23. She had had no previous illnesses of any importance. The present illness had begun about a month before I saw her. She thought that she had got a chill, and returned home and went to bed. There were pains in the abdomen, vomiting, and diarrhœa, and she felt feverish. A medical man was sent for, who kept her in bed and ordered milk diet. The vomiting continued in spite of all treatment. A week later she was removed to a cottage hospital, where she was fed by the bowel. She became greatly emaciated, and remained in this condition for three weeks, steadily vomiting. The diagnosis was one of gastric ulcer. The patient was then seen by me.

On examination she was found to be a pale, emaciated, highly nervous, but obviously very ill young woman, complaining of great pain in her abdomen and continuous vomiting. Her pulse was between 150 and 200, and the temperature was 101° F. On examining her abdomen visible peristalsis was present, passing from the region of the stomach on the left across the abdomen towards the cæcal region. Her bowels had not moved for a week; no flatus was passing. The abdomen was slightly distended; its wall was not abnormally thin. She complained of pain and tenderness on palpation, most marked above the umbilicus and to the left. Nothing could be felt, but her muscles contracted whenever the abdomen was touched, so palpation was difficult. Peristalsis when at rest could be stimulated by stroking the abdomen or by giving the patient a drink of water. Examination of the heart and lungs revealed nothing. The thyroid was not enlarged, and no tremor was present. There were no signs of exophthalmos.

The urine was normal. She had missed one menstrual period, but denied the possibility of pregnancy. Leucocytes 10,000. No differential count was done, but a stained film showed no obvious abnormal blood picture. That night she became much worse; vomiting was now fæcal.

Here was a case of fæcal vomiting, abdominal pain and visible peristalsis, a pulse which was practically uncountable, and a temperature of 101°. At first glance the condition appeared to be one of "acute abdomen," probably acute obstruction high up, and calling urgently for surgical intervention. But in many ways the patient was in an exceedingly bad condition for operation, and certain points about the case made one suspicious of the diagnosis. In the first place, although the patient looked undoubtedly very ill she seemed to have a wonderful amount of strength, she could move about fairly freely in bed, and her expression was not markedly indicative of an acute abdomen. A genuine acute obstruction with a pulse like hers would have been *in extremis*, and she hardly gave one that impression. The question naturally arose, Could the condition of the pulse be accounted for in any other way? Hyperthyroidism suggested itself. Having seen cases of exophthalmic goitre terminate by continuous vomiting I suggested that a thyroid toxin might also account for the vomiting. Working on those grounds I gave as my opinion that the case was one of hyperthyroidism and advocated leaving her alone. For several days the vomiting continued, but although having a fæcal odour it was not so markedly fæcal as on admission.

Suprarenal gland extract and tincture of belladonna were given. The pulse remained much the same, and she was fed with glucose and brandy by the bowel. She was then removed to a side room and put behind screens. From that time a marked improvement set in, the vomiting stopped, the abdominal symptoms disappeared, and the pulse improved considerably. After a few days she was given 3 grains of potassium iodide three times a day. A recurrence of the symptoms might have been expected, but no effect was noticed. On examining her neck a fortnight later I was able to satisfy myself that the thyroid gland was increasing in size. She remained in hospital for one month longer, at the end of which time she had gained 1 st. in weight and her pulse when undisturbed was normally about 100. The menses had not returned.

Two months later the patient came to see me. Her eyes were now distinctly prominent and her thyroid markedly enlarged. The pulse-rate was 105. Her hands showed the typical tremor. She had gained 7 lb. in weight, and expressed herself as feeling quite well but very nervous. Abdominal examination revealed nothing; the menses had not returned. There was now no doubt about the diagnosis: she had developed into a typical case of exophthalmic goitre.

According to Plumer the order of onset of the most important symptoms based on the average of a very large series of cases is as follows:—(1) Cerebral stimulation; (2) vasomotor disturbances of the skin; (3) tremor; (4) mental irritability; (5) tachycardia; (6) loss of strength; (7) cardiac insufficiency; (8) exophthalmos; (9) diarrhœa; (10) vomiting; (11) mental depression; (12) jaundice; and (13) death. As a rule the disease runs a fairly definite course. Severe vomiting usually is a terminal symptom; in fact, quite a large proportion of fatal cases die from severe gastro-intestinal symptoms. How exactly the toxin acts to produce vomiting it is impossible to say; probably through its action on the nervous system when an early symptom and akin to the vomiting of the gastric crisis in tabes. As a terminal symptom the gastro-intestinal symptoms are probably due to the long-continued action of the toxin disturbing and destroying the functions of the digestive organs—in much the same way as the poison of alcohol brings about destruction of the liver and pancreas, &c.

Treatment. — Exophthalmic goitre develops periods of remission of symptoms. For that reason we are apt to claim success to our methods which is not really attributable to them. The use of suprarenal gland extract I have tried repeatedly and have failed to get any results. Rest in bed and isolation are probably much more efficacious than the numerous drugs that have been recommended. Porter's method of injecting 2 drachms of boiling water into one lobe of the gland in very severe cases is well spoken of by those who are in a position to judge. Surgical intervention in very acute cases is out of the question.

Cape Town.

OBSERVATIONS ON THE IMPROVISATION OF APPARATUS IN THE TREATMENT OF CERTAIN FRACTURES IN MODERN WARFARE.

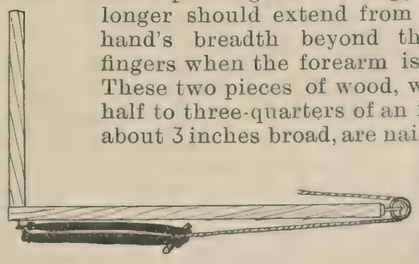
BY J. H. WATSON, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGEON, VICTORIA HOSPITAL, BURNLEY;
AND
T. SNOWBALL, M.B.

III.[1]—FRACTURES OF FOREARM AND METACARPALS.

IT is a well-known fact that fractures of both bones of the forearm in the same plane are apt to be very troublesome if there is not a proper apposition of the fractured ends to one another. If they are displaced towards the interosseous space a bridge of callus frequently fills in the gap and thereby totally hinders the movements of pronation and supination. For this reason alone there is a very useful field for a simple extension apparatus for such fractures. It is hardly necessary to add that in fractures of a single bone no extension apparatus is required.

The method adopted by von Saar at Belgrade was to utilise elastic traction again after the manner of Borchgrevink. A rectangular splint is made of two pieces of soft wood, the shorter piece corresponding to the upper arm. The longer should extend from the elbow to a hand's breadth beyond the tips of the fingers when the forearm is outstretched. These two pieces of wood, which are from half to three-quarters of an inch thick and about 3 inches broad, are nailed together at a right angle. A screw pulley, such as described before, is firmly fixed into the centre of the free edge of the forearm piece and a strong nail is driven from below into the centre of the right angle, leaving about a quarter of an inch projecting. (Fig. 13.)

FIG. 13.



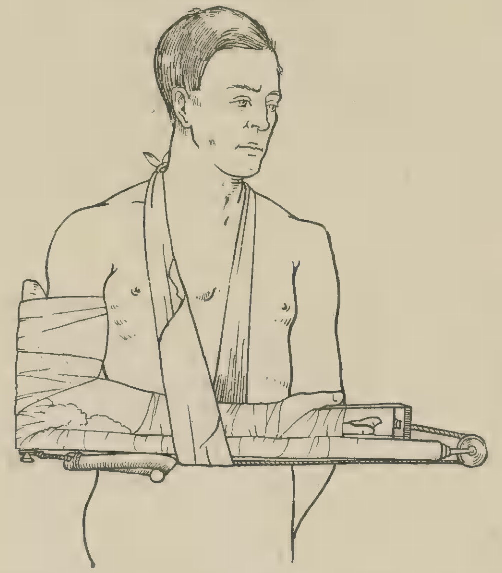
Forearm splint showing elastic traction attached.

---

[1] Nos. I. and II. were published in THE LANCET of Sept. 26th (p. 789) and Oct. 3rd (p. 849) respectively.

Before applying the splint an adhesive plaster is fixed to the forearm in the following way. A strip of plaster about 2 inches wide is applied to the volar and dorsal aspects of the forearm and hand as far as may be necessary, leaving a loop which is lined by another piece of plaster in order to allow unimpeded movements of the fingers. A few circular imbricating turns of leucoplast fix the extension strip to the forearm, and additional strips fix it to the hand if required. The extension string is fastened to a round or rectangular piece of wood, and placed in the loop of the forearm strap, which has been previously perforated for the passage of the string. The string is led over the pulley to the under side of the splint, where it is fixed in the loop of drainage tube, as previously described in the case of the arm; but in this instance the suspending nail is driven into the under side of the splint at the centre of the right-angled junction. A simple sling supports the forearm, so that the weight of the apparatus is eliminated. (Fig. 14.)

FIG. 14.



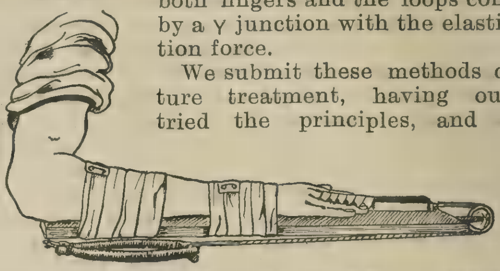
Simple right angle splint applied to forearm with elastic traction.

In applying extension in this way the forearm lies upon the corresponding portion of the splint, which need be only lightly padded, in the position of supination. The mid-position of semi-pronation may be adopted if considered more favourable for the healing of both bones, and for the dressing of any accompanying wounds.

The principle of elastic traction can be simply and efficiently carried out in fractures of the metacarpals by shot, where there is deformity due to the fractured ends projecting backwards and obvious shortening, as follows. A wooden splint, one-third of an inch thick and about the width of the patient's wrist and some two or three inches longer than the forearm, is required. To the opposite ends of this are fixed the requisite suspension nail and screw pulley. The splint is carefully padded on the side to be applied to the forearm—i.e., the under side, the position being one of full pronation. A thin strip of adhesive plaster is placed along the anterior and posterior aspects of the finger corresponding to the injured bone, reaching from the centre of the palm to a corresponding point on the dorsum and leaving a loop for the extension apparatus. The traction plaster is held in place by several circular turns of leucoplast wound round the finger, and if necessary one may be placed round the hand. The splint is now fixed in position to the forearm by several strips of adhesive plaster, which are again covered with ordinary calico bandages to prevent displacement. The elastic traction is attached in the usual way, and the forearm is comfortably slung in a triangular bandage. (Fig. 15.) If two metacarpals are broken extension straps are attached to both fingers and the loops connected by a Y junction with the elastic traction force.

We submit these methods of fracture treatment, having ourselves tried the principles, and having great confidence in their efficiency in suitable cases. Moreover, thanks to the courtesy of Dr. G. F. A. von Saar, one of us (J. H. W.) has seen the various apparatus in use at the Innsbruck Surgical Clinic, and has had the pleasure of observing the excellent clinical results obtained, and of seeing confirmatory röntgenographs. We are not aware that these methods have hitherto been published in the English language, and we are entirely indebted to the writings of Dr. von Saar[2] for the general outline and detail of this paper.

FIG. 15.



Showing application of elastic traction to fracture of metacarpal.
(N.B.—For clearness the usual padding is omitted in the sketch.)

We have to thank Mr. Noel H. Leaver and Mr. G. Grant for the care they have taken in making the various diagrams.

Burnley.

Reviews and Notices of Books.

The Occupational Diseases, their Causation, Symptoms, Treatment, and Prevention.

By W. GILMAN THOMPSON, M.D. London and New York: D. Appleton and Co. 1914. Pp. 724. Illustrated. Price 25s. net.

Dr. Thompson refers in his preface to the fact that this is the first book of its kind to be published in the United States. It is intended primarily for physicians interested in the subject of occupational diseases of modern life and also as a guide for students of social economics, insurance actuaries, and those with special interest in problems of labour legislation and the health of industrial workers. Regarded as a work of reference which, without pretence to exhaustive treatment, gives the main facts about occupational diseases, the book fulfils its purpose with very fair success. It has to be remembered that the concern of the public authorities and of the official medical service in the United States with occupational diseases is much less advanced than in the United Kingdom. Compulsory notification of industrial diseases has only quite recently been introduced, and is at present limited to six States, where the diseases to be reported are mainly limited to poisoning by four metals (lead, arsenic, mercury, and phosphorus, and their compounds), anthrax, and compressed air illness.

---

[2] Ueber Kriegmässige Improvisation von Extensionsverbänden bei Extremitätenfrakturen; Kriegschirurgische Erfahrungen aus den Balkankriegen, 1912–13; Zur Behandlung der Schuszfrakturen der Extremitäten im Kriege.

One of the chief merits of Dr. Thompson's work is the wide range of trades and occupations dealt with, and the number of interesting facts detailed in regard to them. These show that there are many incapacitating diseases of much greater frequency and importance than those to which legislative action in America has so far been limited. Preventive measures need not, of course, in all cases, or even in the majority of cases, consist in legislative and administrative proceedings; much can be done by bringing the cardinal points to the notice of employers and workmen, and making progress by educational means as through writings of this nature.

The sections of the volume relate respectively to general pathology and etiology; general remedial measures, prophylaxis and treatment; diseases due to irritants, under which heading toxic gases and anthrax are considered; diseases due to harmful environment; special occupational diseases; influence of alcohol, syphilis, &c., on occupational diseases; there is a chapter on miscellaneous industries which in one or another way entail risk of special illness. There are numerous illustrations of industrial processes, and the book is clearly written and well printed, though its weight avoirdupois is forbidding. So many occupations are dealt with that reference might have been expected to such occurrences as cow-pox in milkers, small-pox among workers at cotton mills, and Dupuytren's contraction among lace workers. "Pitch warts" perhaps merited a fuller description, and there seems some error in the attribution of tetanus to the bacillus mallei. Dr. Thompson advises that bleeding and transfusion should be adopted in all the more serious cases of carbon monoxide poisoning.

Therapeutics, Dietetics, and Hygiene: An Australian Text-book.

By JOHN WILLIAM SPRINGTHORPE, M.D. Melb., M.R.C.P. Lond., Senior Physician to the Melbourne Hospital. In two volumes. Vol. II.: Therapeutics. Melbourne: James Little. 1914. Pp. 1121 + xcvi. Price 25s.

THE first volume of this work was reviewed in THE LANCET of June 13th last. The portion before us has the same real utility and the same defects of quality as the first. Its chief interest lies in the sketch given of the lines of clinical practice pursued in the wards of the Melbourne Hospital, which shows that good standards of precise work are maintained. But in a work of this pretension it is hardly necessary to include over 60 pages of a hospital pharmacopœia of an ordinary type.

An interesting account of mineral springs in the Commonwealth and New Zealand forms part of the chapter on spring and mineral waters. Such springs are few in number in Australia but very numerous in New Zealand, where many are practically unequipped and almost unused. The climatology is carefully considered by a number of authorities, mostly superintendents of sanatoriums, and this section will prove of service for reference.

The book attempts too much. To introduce a few passages on massage and electrotherapy and the mechanical treatment of spinal curvatures is to overload a volume already diffuse, while to attempt a summary of vaccines and serum therapy in 14 pages is a waste of space. We feel about this really industrious and in many ways useful work that the author's labours have not produced a commensurate result, because he has not written upon a sufficiently definite plan keeping a sense of proportion throughout.

Diagnostic Symptoms in Nervous Diseases.

By EDWARD LIVINGSTON HUNT, Instructor in Neurology and Assistant Chief of Clinic, Medical Department of Columbia University, New York, &c. Illustrated. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 229. Price 6*s*. 6*d*. net.

IN this book the main varieties of neurological symptoms or symptom-complexes are handled under such headings as deformities, paralysis, tremors, trophic disorders, gaits, ataxia, convulsions, disturbances of speech, and so on. As a result the student is confronted with lists of nervous diseases in each of which, for instance, tremor may occur, and he may come across them, or some of them, later as affections in which disturbances of gait may occur. Thus he gets but an interrupted view of any particular disease, although, no doubt, he may be able to combine his knowledge of symptoms into a synthetic study of the diseases themselves.

It is questionable whether such methods are profitable. He who is already fairly familiar with neurology might conceivably find advantage in refreshing his memory by consulting such a book of reference as this: it does not disdain tips—e.g., in the Argyll Robertson pupil, "remember the two last letters of the word Argyll—L L means loss of light." Its value, however, would be greater if it were more complete and if there were fewer statements to which exception might be taken. There is a chapter on the eye, but the ear and the labyrinth seem to be ignored; we can find no mention of vertigo. Spinal cord localisation, vertical and transverse, does not appear to be discussed, but this is one of the common diagnostic problems with which the student is faced.

The desire of the author to make his book concise is, no doubt, responsible for some of the misleading statements which it contains. Were it amplified its usefulness would be increased.

A Manual of Surgical Treatment.

By Sir W. WATSON CHEYNE, Bart., C.B., D.Sc., LL D., F.R.C S. Eng., F.R S.; and F. F. BURGHARD, M.S. Lond., F.R.C.S. Eng. New edition, entirely revised and largely rewritten with the assistance of T. P. LEGG, M.S. Lond., F.R.C.S. Eng., and ARTHUR EDMUNDS, M.S. Lond., F.R.C.S. Eng. In five volumes. Vol. V. London, New York, Bombay, and Calcutta: Longmans, Green, and Co. Pp. 619. Price 21*s*. net.

THIS is the concluding volume of the system of surgery which may be called the King's College Surgery, as all connected with it are on the surgical staff of King's College Hospital. It deals first with the surgery of the pancreas, and naturally the main subjects treated are acute pancreatitis and pancreatic cysts. Then follow chapters on the treatment of injuries and diseases of the liver and the biliary passages. In this connexion it is of interest to see it stated that, in cases of operation on the gall-bladder, if jaundice is present, it will be well to give lactate of calcium the day before the operation. The belief in the efficacy of calcium salts in such cases is not at all so widely spread as it was not very long ago; the basis of its administration was theoretical, and practice has hardly supported the theory. The chapter on the surgery of the spleen is short, but contains all that is necessary.

In the section dealing with the surgery of the neck probably the most important portion is that treating of the removal of cervical ribs; the authors describe both the anterior and the posterior operations, but they do not say which they prefer. The section dealing with the surgery of the mammary gland is especially good. The authors speak favourably of repeated courses of X ray treatment over the part from which a carcinoma of the breast has been removed, the first course beginning about six weeks after the operation, and they are inclined to think that this treatment has a deterrent effect on recurrences.

This volume also contains an account of the surgery of the genito-urinary organs; the procedures here are excellently described and fully representative of present-day surgery. The final chapter deals with those operations on the female genital organs which may be found necessary in the course of an ordinary laparotomy.

LIBRARY TABLE.

Walt Whitman's Anomaly. By W. C. RIVERS. London: George Allen and Co. Pp. 70. Price 2*s.* 6*d.* Sale limited to legal and medical professions.—The invitation of Shakespeare's clown, "Will you ha' the truth on't?" is a long time getting accepted. At some future date, perhaps now not so far away, the object of medicine will be recognised by public opinion to be the pursuit of all pertinent knowledge, instead of, as at present, therapeutics—with such prophylaxis as comes up in the course of therapeutically directed research. Then what are now the *Grenzgebiete* of medicine will better their provincial status. That one of them has lately made distinct steps in this direction is, however, probably due to the fact that Freud's work has revealed an interesting addition to the treatment of hysteria and neuroses generally. Those who read Freud soon perceive for themselves that there is implied a working acquaintance with sex problems, a branch of knowledge which, arising in the last 30 years, has rather outstripped general medical cognisance. This is where we think the little work under notice is likely to be useful to medical and medico-legal readers. Its general thesis is that a male sexual invert is a woman in a man's skin, a mental organisation changed in certain directions pervading the whole being; and the suggestion is that inversion is a mistake that nature is particularly apt to make in the case of men of genius or great talent. There is clearly considerable intellectual interest attaching to these facts, while medical men, who do not need reminding of the dangers of extreme democracy, may find here part of the great democratic poet's message rooted in what another critic, in finely perceptive phrase, has called "the instinctive anarchism of the degenerate." The book, though slight, is pithy and discerning, and deserves on the whole the recognition accorded it in important quarters. For ourselves, we find it hard to discriminate how far Mr. Rivers proves his point, or to what extent his "facts" are generally accepted. In any event, the memoir merely adduces one more case, which is far from being the same thing as proving a general thesis. For this reason we regret that the name of the subject was introduced, for the facts we think might quite well have been brought forward in a form so veiled that only those professionally interested and competent to form a discreet opinion would have pierced the veil.

Examination of the Urine and other Clinical Side-Room Methods (late Husband's). By ANDREW FERGUS HEWAT, M.B., Ch.B., M.R.C.P. Edin., Tutor in Clinical Medicine, University of Edinburgh. Fifth edition. Edinburgh: E. and S. Livingstone. 1914. Pp. 212. Price 1*s.* 6*d.* net.—This excellent little book gives the various methods in use for the clinical examination of the urine, blood, sputum, pus, gastric contents, and fæces. The part dealing with the urine (125 pages) is practically a rewriting of the fourth edition of Husband's "The Urine in Health and Disease." The other sections are new. The book is brought right up to date. A very valuable feature is that the fallacies of certain tests are carefully pointed out. The book can be commended to medical students to accompany their practical class work in the subject, and it will be hardly less useful to general practitioners out of touch with modern laboratory methods in clinical medicine. We note that the author quotes the not universally known term "side-room" in the text. It might have been advisable to do so also in the title. It is too suggestive of a misprint for "sick-room."

Bacteriology for Nurses. By ISABEL MCISAAC, R.N. Second edition, revised. New York: The Macmillan Company. 1914. Pp. 179. Price 5*s.* 6*d.* net. —In reviewing the first edition of this work we stated that the author puts the case for a knowledge of bacteriology by nurses extremely well, and produces a clear and accurate, if elementary, account thereof, including directions for so much working knowledge as is necessary for a satisfactory grasp of aseptic technique and an understanding of the sources and *modus operandi* of infection. These remarks equally apply to the present edition; but we still note the statement (p. 11) that "spores possess an extraordinary resistance to heat (70°–100° C.)," to which we took exception in our previous review. For the benefit of the English reader we may point out that "R.N." in the United States stands for registered nurse, not Royal Navy.

JOURNALS AND MAGAZINES.

The Annals of Tropical Medicine and Parasitology. Vol. VIII., No. 2.—This may be regarded as an Entamœbiasis number of the Annals, for of the total 235 pages which are comprised in it all but 10 are devoted to the subject of entamœbiasis in its various aspects. The chief contribution is furnished by Dr. William M. James, physician to the Ancon Hospital, entitled A Study of the Entamœbæ of Man in the Panama Canal Zone, illustrated with six coloured plates. This paper gives a summary of the present state of our knowledge of amœbic dysentery, and supplies also the results of the observations made by Dr. James and his colleagues as regards dysentery in the Isthmus of Panama. The author presents his facts and conclusions on the identification and classification of human entamœbæ more from the point of view of the practising physician than from that of the protozoologist. Although, as a result of his studies, Dr. James is of opinion that there are only two species of entamœbæ found in man—namely, a pathogenic species, E. histolytica, the cycle of which ends in a four-nucleated cyst, and a non-pathogenic species, E. coli, the cycle of which ends in an eight-nucleated cyst—he finds it convenient in writing of the types of entamœbæ met with to call them by the names by which they are commonly known at the present time. So that when writing of E. histolytica, E. tetragena, and E. minuta he desires it to be understood as describing what appears to him to be different types of the same species. Dr. James, however, admits that the classification of species is not yet fully determined, and that this task is one for the protozoologist rather than for the clinician.—The next original article is on the dysenteries in the Canal Zone with special reference to amœbic dysentery, by Dr. W. E. Deeks, chief of the medical clinic of the Ancon Hospital. This latter form of the disease, of which E. histolytica is the specific organism, Dr. Deeks thinks, has probably a water-borne origin; there is, he says, no endemic centre of the malady, and immunity, as we understand it, does not exist. Age, locality, nationality, or occupation plays no part in its etiology. The pathological lesions are peculiar and characteristic. As regards treatment, the author regards amœbicidal irrigations as useless; in his opinion the bismuth-milk-saline method of treatment (which was described in THE LANCET of Dec. 23rd, 1911) gives in almost all instances "splendid" results if administered in the proper way. In a second paper Dr. Deeks discusses the use of emetine in amœbic dysentery. It appears that when he wrote his first paper recommending the subnitrate of bismuth treatment the brilliant successes with emetine obtained by Colonel Sir L. Rogers, I.M.S., in Calcutta had not been published. Dr. Deeks therefore made trial of the new remedy at the Ancon Hospital. His observations show, however, that in 12 patients in whom emetine was used, 6 had relapses, though the drug greatly relieved the symptoms in all the cases. The author has now arrived at the conclusion that a combination of the two remedies, emetine and bismuth, would be more effective. Emetine probably acts as a direct poison to the amœbæ, while bismuth, in all likelihood, has the power of destroying symbiotic organisms necessary for the growth of the amœbæ in the intestinal tract. A third paper is contributed by Dr. Deeks on a six-days' fever in Panama, a malady hitherto unrecognised in the Western Hemisphere. It runs a characteristic febrile course, attended by a rash probably allied to the exanthemata, but the nature of the infection is not yet known. Appended to the paper are seven illustrative temperature charts. We may mention that in THE LANCET of Sept. 13th, 1913, some comments were offered on a preliminary note which Dr. Deeks had published in the *Journal of the American Medical Association* on this new form of fever, the precise nature of which still remains obscure and requires further investigation.

Malaria e Malattie dei Paesi Caldi. Anno V. Fasc. III. June 20th. Via Farini, Rome.—The May–June number of this publication, the last to reach this office from the Italian publishers, contains an article by Professor Arnaldo Cantani, of Naples, on the Action of the Micrococcus Melitensis on the Central Nervous System, and gives details of three cases—one of meningismus, a second of chorea, and a third of psychosis where maniacal attacks alternated with a condition of hebetude.—Dr. F. Giugni, of Rome, contributes a paper on the Vitality and Development of the Leishman-Donovan Body in Cultures. He found that growth took place only in blood media deprived of serum. He is of opinion that the rarity of the parasite in peripheral blood in comparison with its presence in splenic blood may be due to some peculiar property of the splenic serum.—Dr. C. Russo describes his experiments with trypoflavin as a cure for trypanosomiasis.—There are other articles on the Temperature in Ankylostomiasis, the Clinical Course of Mediterranean Fever, Oriental Boil, and the Transmission of Leishmaniasis.

METROPOLITAN WATER BOARD:

EIGHTH ANNUAL REPORT ON THE LONDON WATER AND TENTH REPORT ON RESEARCH WORK.[1]

Dr. A. C. Houston's eighth annual report deals with analyses of London water during the 12 months ending July 31st, 1914. The results are tabulated on the same lines as in previous reports, and they show that, on the whole, the quality of the London water was up to its average. A prominent feature of this, as of Dr. Houston's previous reports, is the emphasis laid on the bacillus coli test. The raw waters used for the supply of London afford a remarkable instance of the wide range of this index. Thus, while 94 per cent. of the samples of raw water taken from the Kent wells during the past year showed no typical bacillus coli in 100 c.c., no less than half of the samples of raw water taken from the Thames and Lea contained this microbe in 0·1 c.c. But in spite of the fact that the fæcal microbe in question is often a thousand times more abundant in the river water than in the Kent water, it is interesting to note that this river water is so purified in practice that over 80 per cent. of the samples of it, as delivered to consumers, contain no bacillus coli in 100 c.c. This, therefore, is the bacteriological standard of purity which Dr. Houston recommends for general adoption in the case of a potable water.

Dr. Houston's tenth report on research work contains a further instalment of his important investigations in connexion with the purification of water. The present volume is subdivided into seven sections, dealing with the following subjects: 1. Search for pathogenic microbes in river water and sewage. 2. Methods for the isolation of the typhoid bacillus. 3. Influence of temperature on the vitality of the typhoid bacillus. 4. Study of streptococci in excremental matters. 5. Value of storage. 6. Lime as a bactericidal agent. 7. Vitality of the cholera vibrio outside the body. This research report should be carefully studied by those who have to deal with water-supplies. In the first place, it is comforting to see that in spite of elaborate and strictly controlled quantitative investigations Dr. Houston has not found either the typhoid bacillus or Gärtner's bacillus in the London raw river water. After detailed comparison, he finds that malachite green solid medium gives best results for isolation of the typhoid bacillus. The annual range of temperature of the London water varies from 5 to 14·5° C. Dr. Houston has shown that the typhoid bacillus survives longer in water at the lower temperature, and accordingly he points out that it is especially desirable that during the five cold months (November–March) the raw river water should be adequately stored antecedent to filtration. A quantitative investigation of the acid-producing capacity of streptococci isolated from the fæces of man and animals respectively does not furnish, according to Dr. Houston, more than somewhat doubtful evidence for the purpose of their differentiation. His experiments on the effect of storage in freeing a water of undesirable bacteria lead Dr. Houston to the conclusion that this beneficial action is due to actual death of these bacteria, and not merely to their mechanical separation. According to the bacillus coli index, ordinary purification of raw river water by storage and filtration improves it about 1000 times; further experiments with Dr. Houston's excess lime method, however, show that by this process raw river water can be purified on a practical scale at least 10,000 to 100,000 times. The report ends with a reprint of the recent work of Major E. D. W. Greig, I.M.S., on the vitality of the cholera vibrio outside the body. Greig's results, which were obtained in India, confirm those of Dr. Houston with the typhoid bacillus in London. Both micro-organisms survive for a much shorter time outside the body in hot weather than in cold.

ANNUAL REPORT OF THE METROPOLITAN ASYLUMS BOARD FOR 1913.

THE latest volume of this valuable series continues the medical, statistical, financial, and administrative reports and tables of previous years, and it also affords further illustration of the continued expansion of the functions which the Metropolitan Asylums Board exercises in connexion with the sick persons in London for whom institutional treatment or care has to be provided.

Mental Defectives.—Children's Institutions.

Accommodation is provided by the Board for both feeble-minded and "improvable" imbeciles and for "unimprovable" imbeciles. The latter, owing to the absence of any outlet for the children as they become adults, require more and more accommodation, and Tooting Bec Asylum, which is used for the adult cases, is now to be extended so as to increase the available beds from 1114 to 1727. Further schemes for the accommodation of the unimprovable children, temporarily accommodated at a hospital intended, and sometimes needed, for infectious disease, are also in progress. The report hints that the "improvable" class, in consequence of the operation of the Mental Deficiency Act, may shortly need new provision also.

The Board is responsible for Poor-law children who are "sick, debilitated, or convalescent," and those who suffer from contagious diseases of the eye and skin

---

[1] By Dr. A. C. Houston. London: Charles Straker and Sons. 1914. Price of each 2s. 6d.

It has been found that the special children's hospitals, particularly the Park Hospital, have been overtaxed by cases which are really in no need of the trained nursing and other conditions which these hospitals provide, and an effort has been made, as a result of inquiries made for the Board by Dr. H. E. Cuff, to limit the use of these hospitals as far as possible to children requiring operations, non-tuberculous bone and joint disease, non-pulmonary tuberculosis in its various forms, cases of lateral curvature requiring spinal exercises, and paralytic cases. The Board's hospital at Margate, where excellent results are said to have been achieved in the case of children with tuberculous joints, bones, and glands, is to be rebuilt and enlarged as a sanatorium for children providing 270 beds, largely in open-air verandahs, to which small indoor wards will be adjuncts. Of the children with ringworm in the special section of the Park Hospital, Lewisham, in 1913, 631 were treated entirely by X rays. Dr. H. G. Critchley, the assistant physician in charge of this treatment, states that, taking a date at random and 100 consecutive cases, the number of days elapsing between the date of X ray administration and the date of the certificate of fitness for discharge is 30·2.

Casual Wards: Deterrent Measures.

The policy of placing the different casual wards in London under the Board continues to be justified by the results obtained. The method adopted by the Board is to assist as many as possible of the casual poor without taking them into the casual wards at all, by passing them on to coöperating voluntary agencies, who in many cases have enabled them to return to the normal life of self-supporting citizens. There remains, however, a residuum of "able-bodied and physically fit young persons who deliberately refuse help and have determined to make themselves a burden on the community." The numbers of these persons rise with startling rapidity with any improvement of the conditions under which shelter and maintenance can be obtained at the public expense. The casual wards committee observe that the community undertakes to restrain and deter the drunkard, the petty thief, and the minor criminal, whose offence is much less vital than that of the man who insists on making himself a perpetual public burden, and they urge that restrictive and deterrent measures against all such persons have very ample justification. 879 inmates of casual wards were charged during 1913 at the metropolitan police-courts for neglecting or refusing to work or for other offences, and most of these were convicted, but it may be doubted whether these convictions have the deterrent results which the committee desire to see.

Acute Infectious Diseases.

17,544 cases of scarlet fever were notified in London during the year, and 15,010 cases of the disease were admitted to the infectious diseases hospitals. The case mortality rate was as low as 1·2 per cent., lower by 1·5 than the average for the preceding ten years. In the medical supplement to the report, edited by Dr. F. M. Turner and Dr. J. E. Beggs, the following figures are given in regard to "completed" cases in illustration of the decline in the number of cases of septic scarlet fever.

—	1909.	1911.	1913.
Case mortality	2·33	1·94	1·25
Otitis...	12·70	11·42	8·81
Adenitis (early suppurative)	0·83	0·69	0·17
,, of convalescence, simple...	7·68	6·36	4·95
,, ,, suppurative ...	1·26	1·02	0·77
Bronchopneumonia	0·52	0·45	0·31
Ulcerative stomatitis	0·96	0·73	0·51

The 5076 admissions for diphtheria at all ages included 1998 children under 5; the all-age case mortality was 6·5 and that under 5 was 10·2. This is stated to be the lowest rate on record, 2·4 below the all-age average of the preceding 10 years. Certain cases "certified after the bacteriological test only" have been excluded from these figures. The preparation of diphtheria antitoxin for the Board has continued, and is reported on by Dr. G. Sims Woodhead and Dr. G. E. Cartwright Wood. An interesting appendix by Dr. J. D. Rolleston and Dr. C. R. Macleod, assistant medical officers of the Grove Hospital, describes the technique and advantages of intramuscular injections of antitoxin, and is made the subject of an annotation this week.

The admissions in 1913 for enteric fever were 238; puerperal fever, 58; poliomyelitis, 11; and cerebro-spinal fever, 5. The measles cases admitted were 3400, of which 2744 were children under 5. The all-age mortality rate was 12·6, and that under 5 was 14·6. The Statistical Committee state that it should be remembered that the high mortality rates from this disease at the Board's hospitals are the result of the special class of cases admitted. Unlike scarlet fever and diphtheria, measles admissions are still limited to children of the poorest class and to urgent and necessitous cases recommended by medical officers of health. Similar considerations apply to the 1044 cases of whooping-cough (at all ages) admitted during 1913, of which the case mortality was 13·1 per cent.

As regards the average length of residence of patients who completed their recovery or died at the Board's town hospitals during the year, the figures are for scarlet fever 58·7 days; diphtheria, 57·3 days; enteric fever, 59·2 days; measles, 42·6 days; and whooping-cough, 91·4 days. The averages naturally vary in different institutions. Separate figures are given for those cases which were transferred to convalescent institutions.

Only one case of small-pox was admitted during the year. With regard to Joyce Green Hospital, the main institution set aside for small-pox, Dr. T. F. Ricketts points out in his report that its use during an interepidemic period of diseases other than small-pox has the great advantage that a nursing staff is permanently in evidence and available for small-pox should the hospital be suddenly required for its original purpose. In the present conditions of the nursing service Dr. Ricketts doubts if the necessary nurses could be obtained at short notice.

Tuberculosis.

Various negotiations between the Board and the Local Government Board, London County Council, and London Insurance Committee, as to the provision of residential institutions for tuberculosis, are detailed in the report. The Downs School at Sutton, formerly occupied by sick children, was converted into a male sanatorium and opened in February, 1913, 1213 cases being admitted up to the end of the year. Part of the Northern Hospital was opened in March, 1913, accommodating 192 male and 517 female tuberculosis cases. Reports by the respective medical superintendents are included in the volume, and naturally relate principally to organisation. In regard to the Downs Sanatorium, Dr. A. F. Cameron refers to the great difficulties which have to be overcome in converting an old institution to a purpose very different from that for which it was intended. These difficulties have been particularly great in consequence of the relatively small area of land attached to the institution.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

At the extraordinary Comitia held on Thursday, Sept. 20th, Sir Thomas Barlow, Bart., K.C.V.O., the President, in the chair, licences to practise physic were granted to 122 candidates who had passed the required examinations.

The following communications were received: 1. From the secretary of the Royal College of Surgeons of England, dated July 31st last, reporting proceedings of the Council of that College upon July 30th. 2. From the secretary of the Ninth International Penitentiary Congress, to be held in London in July, 1915, asking the College to nominate a representative upon the National Committee of the Congress. It was resolved to request the President to nominate a representative should the Congress take place.

The College resolved not to hold the usual dinner this year on the evening of the Harveian Commemoration (Monday, Oct. 19th), but that the oration should be delivered as announced.

THE LANCET.

LONDON: SATURDAY, OCTOBER 10, 1914.

The British Pharmacopœia, 1914.

THE publication of a new issue of the British Pharmacopœia is an event of real importance both to medical practitioners and to pharmacists. The Medical Act of 1858, Section 54, enacts that "the General Council shall cause to be published under their direction a Book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed, and containing such other matter and things relating thereto as the General Council shall think fit." The issue of 1914 is the fifth British Pharmacopœia, the fourth having appeared in 1898. The Council has desired in each issue to afford to the members of the medical profession, and to those engaged in the preparation of medicines throughout the British Empire, one uniform standard and guide whereby the nature and composition of substances to be used in medicine may be ascertained and determined. In the preparation of this edition the Pharmacopœia Committee of the General Medical Council has been throughout assisted by a strong Committee of Reference in Pharmacy, appointed by the Pharmaceutical Societies of Great Britain and Ireland; by highly scientific Reference Committees in Chemistry and Botany; and by official information derived from India and our colonies. It behoves all medical practitioners and pharmacists to make themselves acquainted with the principal changes and additions which have been made in the prescribing and preparation of remedies since the issue of 1898 was published. In another column we publish an article dealing with the subject mainly from a pharmaceutical point of view, confining ourselves here to points of particular interest to those engaged in medical practice.

The first point we have to note is that the metric system is employed for all the pharmaceutical and analytical computations in the volume, and that imperial equivalents are no longer given. This will naturally compel all pharmacists to adopt the metric system, and will at first perhaps cause some complaints, but the final result will naturally tend to international uniformity. In the specification of doses both systems are employed, but there is evidently an expectation that in the near future the metric system will be generally adopted by British prescribers. The older practitioners, not having acquired the use of the metric system recently or thoroughly through work in chemical or pathological laboratories, will find some difficulty in adapting their thoughts to the use of grammes and centigrammes instead of grains or fractions thereof, but students and young medical men have already accustomed themselves to learning the doses of drugs according to the metric system as well as to the more familiar imperial system. When once mastered the former possesses many advantages over the latter. Another significant recommendation is that the symbols ʒj and ℥j should be discontinued. There will certainly be considerable difficulty to many practitioners caused by the adoption of the new style, and it will be necessary for many at first to be exceedingly careful over dosage. And with regard to dosage we are glad to see the prefatory remark: "It must be clearly understood that the 'doses' mentioned in the Pharmacopœia are not authoritatively enjoined by the Council as binding upon prescribers." It has never been sufficiently understood that the dosage of the Pharmacopœia is only intended as a guide. The experience of individual practitioners teaches them the most effective quantities which may be prescribed, and how far the average doses may be exceeded or diminished in particular cases. Doses in practice are frequently larger than those suggested by the official work, and numerous instances will at once present themselves to our readers. For instance, the dose of camphor is given as 2 to 5 grains (using the old system), whereas in cases of cardiac failure, especially in pneumonia, 30 grains may be injected in sterilised almond oil. The medical practitioner is left by the express instructions of the Pharmacopœia Committee of the General Medical Council to exercise his own judgment and act on his own responsibility in respect of the amount of any therapeutic agent he may prescribe or administer. When an unusually large dose is prescribed it is the duty of the pharmacist or dispenser to satisfy himself that the prescriber's intention has been correctly interpreted. A highly important series of alterations will be found in the new edition—namely, the changes in strength of certain preparations. Some of these modifications are discussed by the Pharmacopœia Committee. From the point of view of the practitioner these changes require careful study, notably in respect to tinctures in daily use. Certain of these have been diminished in strength—as, for instance, the tincture of nux vomica—whilst others have been increased, the tincture of strophanthus being four times as strong as before. Attention is drawn to these alterations in a paragraph of different type under the heading of each preparation, so that they are easily detected, the explanation of the change being usually indicated by the statement that the new preparation is of approximately the same strength as the tincture of the International Agreement. The International Agreement is a series of recommendations adopted at an international conference respecting the unification of the formulæ for potent drugs and preparations in the several national pharmacopœias. The conference was held at Brussels in 1902, and the recommendations were adopted in 1906 by the participating states.

It has always been the custom to freely employ contractions of Latin words in writing prescriptions, and we are glad to see that the difficulties arising from the vagaries of prescribers are now taken note of. Hitherto the form and extent of such contractions have been left to individuals. Now an attempt has been made to arrive at uniformity, and in the new Pharmacopœia is a list of abbreviated Latin names of official drugs. Whether these abbreviations will meet with general adoption is certainly open to doubt, but if they gradually come into use a source of confusion will be avoided. There is strong evidence throughout the whole book that the greatest care has been devoted to its compilation, and the thanks and congratulations of the profession are due to the members of the Pharmacopœia Committee of the General Medical Council, who have been entrusted with the arduous undertaking. The Committee has very rightly expressed to the Council its high appreciation of the manner in which Dr. NESTOR TIRARD has performed his responsible duties as senior editor of the British Pharmacopœia and secretary to the Committee since his appointment to the office of secretary in 1895. This testimony will be supported by the medical profession at large.

◆

The German Medical Profession and Preparations for War.

MOST of the letters which the American medical journals are wont to publish from special correspondents in Germany have ceased to appear, but the *Journal of the American Medical Association* has published a letter from a contributor in Berlin dated August 8th but delayed in transmission. From this it appears that not only the regular army surgeons, but also the whole reserve, were immediately mobilised. In addition, a large number of civil practitioners, some of whom have performed military service, while others have not, have placed themselves at the disposal of the War Department, mainly, it is said, for service in home hospitals when these are organised. Calculating on the basis of the Franco-Prussian war, it is estimated that there are 12,000 practitioners serving the army. Senior students are being excused their final examination in order that they may serve with the army as surgeons, and these are perhaps the medical men referred to in a communication which we publish elsewhere from a correspondent writing from Switzerland. To meet the shortage in civil practitioners which might be created the representatives of the profession in the neighbourhood of Berlin and in other districts have required practitioners at home to take over the practices of their colleagues at the war free of charge. Loans are also being issued by the medical organisations to needy families of practitioners without charging interest, and the funds of the Leipziger Verband, raised for the insurance fight, and amounting to about £50,000, have been devoted to the same purpose. The German public is maintaining a fund to provide care for the wounded; this is said to have reached a sum of £50,000, including a contribution of about £5000 from the KAISER, within the first ten days of mobilisation. No doubt the fund has by this time reached a high figure, as undoubtedly the numbers of wounded are very large.

For the reception of the wounded arrangements very similar to our own have been made. There are the military hospitals and also the State and municipal hospitals. Private hospitals and the castles of the nobility have also been offered freely. On July 31st, before war had been declared between Germany and Russia, an Imperial Order was issued forbidding the export of material for dressings and remedies, as well as surgical instruments and apparatus, until further notice. On the same date a list of articles included in this embargo was published. These steps immediately produced a rise of prices in Austria, where the wholesale druggists issued a circular pointing out that this was inevitable. An American correspondent of the *Journal of the American Medical Association* calls attention to the fact that, owing to the departure of their employees for active service, most of the surgical instrument factories in Germany are closed, and points out that this is America's opportunity. British manufacturers of surgical instruments are also realising that a chance is being offered of securing foreign and home orders that have hitherto gone to Germany, though the reduction of prices to the German scale will certainly cause considerable difficulty in some directions.

Annotations.

"Ne quid nimis."

THE ROYAL SOCIETY OF MEDICINE AND THE WAR.

THE influence of the war is making itself felt everywhere. A most noticeable feature in the Calendar of the Royal Society of Medicine for 1914–15 is the marked reduction in the total number of section meetings announced for the forthcoming session. The reason is obvious. A war of the present magnitude not only calls for a large increase in the establishment of regular medical officers at the front, but Red Cross and other voluntary societies, both abroad and at home, take away from civil life a considerable number of medical men. Then there is a vast number of Territorial medical officers called up, and a great deal of administrative work being done to which all classes in the medical profession are freely contributing their share in personal service. The patriotic response to the call of the nation has been quite as enthusiastic in the medical profession as in any other walk of life, and we may add with pardonable pride that from all quarters comes a whole-hearted testimony to the value of its services and to the competence and devotion to duty of its members. The exiguousness of this year's calendar of the Royal Society of Medicine is thus honourably accounted for. But the temporarily unproductive season of sowing will produce in the future a richer harvest, probably, than has ever followed a war—a harvest of observations and of medical and surgical principles founded thereupon, which will extend scientific knowledge in its application to the healing art. Thus not only military medical science but suffering humanity at large will derive incalculable benefits. All honour to our medical soldiers, who, as the published casualty lists demonstrate, while engaged in the saving, not the destruction, of life, cheerfully and bravely pay toll of their own body in a proportion nowise inferior to that of their "combatant" comrades. The society's programme is, however, by no means a negligible one, in spite of the difficulties mentioned, and it may be worthy of special notice that one of our Indian colleagues, Professor Chunder Bose, D.Sc., of Calcutta University, is announced to give a demonstration before the Fellows on Oct. 30th, at 5 P.M., on the Modification of Response in Plants under the Action of Drugs. We trust that an adequate attendance will reward him.

THE CULT OF ÆSCULAPIUS IN GREECE AND ITALY.

IN the Proceedings of the Accademia dei Lincei Signor A. Maiuri once discussed an inscription upon an ex-voto set up in the sanctuary of Æsculapius upon the Esquiline hill in Rome. The inscription occurs upon the base of an offering representing Æsculapius as an infant, and erected, so the inscription states, by Nicomedes, a physician who is known also from a previously edited Greek inscription. The date of the text, if it could be ascertained with certainty, might fix the time of the building or rebuilding by Diocletian of the temple of Æsculapius, inside Trajan's Baths; but the dedication by Nicomedes may be a copy of an ancient text, and the statue also a replica of a former one executed to be placed in the Diocletian temple in place of one known to have been in an older shrine of the god of healing in Rome. M. F. Versakes, who is endeavouring to establish with greater accuracy the topography of ancient Athens, while tracing the partly covered foundations of the outer wall of the Asclepieum there, came upon those of a still earlier sanctuary beneath them. These enclose a larger space than the Asclepieum boundary, and so mark the precincts of the older Eleusinium. The first shrine of Asclepios was probably in the western part of this larger enclosed space, but after the god was invited to Athens as guest and protector he appears to have appropriated most of the eastern part of the Eleusinium, leaving the western space, near the entrance to the Acropolis, to serve as the Eleusinium for later times. Some years ago, from very ancient Greek inscriptions discovered in a small temple ruin upon the Acropolis at Athens, Herr Koerte considered it proved that the god of healing, of whose worship Sophocles was a priest, was Amynos, who in B.C. 420, on the introduction of Asclepios, was associated in worship with the latter deity, and with Hygeia. Sophocles then became an official of the Asclepios cult. In a recent number of the *Journal of the German Archæological School at Athens*, however, Herr Schmidt has endeavoured to show that the medical deity to whom Sophocles was first a priest was Halon, who is to be identified with Halissothius. The cult, like those of many early deities of healing, was connected with a spring. The Latin legend sets forth that in B.C. 293 an oracle commanded the Romans to send an embassy to Epidaurus to find out what god was adored there, and that in consequence of that deputation Æsculapius came to Rome in the form of a serpent. This story may have originated from a statue of the deity having been transported to Italy bearing with the deity's own image his customary attendant serpent. As an interesting commentary upon this theory the evidence derivable from inscriptions found in Italy tends to show that Æsculapius did not, as was stated by Roman annalists, arrive in Rome direct from his most important and ancient shrine at Epidaurus, but by some more circuitous route and from some intervening sanctuary, probably in Southern Italy. In support of this view it is noticeable that in the dedicational inscriptions to him found in his early shrine upon the island in the Tiber his name is spelled Aiscolapio, indicating that his cult came there from some Greek sanctuary whereat it was written Αἰσκλαπιός. Now this spelling had disappeared at Epidaurus as early as the fifth century B.C., and had given place to 'Ασκλαπιός, later 'Ασκληπιός. The route by which the worship of Æsculapius really reached Rome appears to have been *viâ* Tarentum, for an inscription upon a vase from that place spells the name Aislapi. Moreover, Varro, when writing of a picture representing a chariot race in which the contestants are Tarentines, tells us the scene was at an old temple of Æsculapius. Again, Julian, in the fourth century of our era, wrote of the Æsculapian cult as coming from Ionia to Tarentum and thence to Rome, and as the peace with Rome and Tarentum was made in B.C. 293, this agrees with the date of the legendary arrival of the deity in Rome from Greece. It would seem likely, therefore, that the worship of Æsculapius came to Tarentum, in Italy, from Greece at a very early date, while the deity's name was spelt in its archaic form, and later journeyed up the Italian peninsula from the south to Rome.

THE INTRAMUSCULAR INJECTION OF ANTITOXIC SERUMS.

A STRONG plea for the intramuscular rather than the subcutaneous or intravenous injection of antitoxic serums is advanced by J. D. Rolleston and C. Macleod,[1] who have employed it with success during the last six months in 339 patients with diphtheria. It is pointed out that the absorption of the antitoxin into the blood is, naturally, most rapid when the serum is given by intravenous injection; but the absorption after deep injection into the muscles of the thigh is only a little less rapid, and proceeds very much—from 3 to 20 times —faster than does absorption after subcutaneous injection. The technique advised is very simple. Without preliminary washing the outer side of the thigh in its middle third is painted with a 2 per cent. solution of iodine, the needle is driven deep into the body of the Vastus externus, and the injection is given in the ordinary way. 20,000 units, or 50 c.c., can be readily injected thus even in small children. Directly the needle has been withdrawn after injection the site of puncture is again painted with iodine solution and a collodion dressing applied. The thigh is to be preferred to the gluteal region, not only because there is less probability of injuring important vessels or nerves, but also because the thigh muscles are much more compact and exercise greater pressure on the injected fluid, rendering absorption more rapid. No suppuration was noted after any of the 412 injections administered. On the other hand, the benefit of the rapid absorption thus obtained was shown by the lesser incidence of post-diphtheritic paralysis, especially of a severe kind, in the patients treated by this method.

SUPERSTITIONS IN TIME OF WAR.

TERRIBLE as it is, a state of war has certain compensations for the student of custom, for it often leads to a recrudescence of interesting superstitions concerning self-preservation and health. These mostly date from a remote antiquity. The wearing of charms, for instance, and the employment of various forms of mascots to ward off death or disease are very ancient, and are still not unknown among those European soldiers whom primary education has not sophisticated. The scapulary, or fragment of holy cloth, is worn next the heart by all kinds of fighting men, whose ancestors marched in procession under banners that were supposed to ward off plague when epidemics were raging in mediæval cities. But it is not only in the tented field that primitive superstitions are reborn. Relics of antique custom and belief spring up almost everywhere in periods of stress such as the present. From Dorsetshire, for instance, home until lately of "conjurors" and "wise women," who acted as tribal medicine men among a peasantry of Goidelic descent, there comes to us anonymously a "snowball" prayer, which we are asked to copy out nine times and to forward to nine different destinations within nine days." "This prayer," says the anonymous sender, "has been sent to me and is to be sent to all the world. It was said in ancient times that all who passed it by would meet with some misfortune, and that all who wrote it would be free from calamity." It is a simple non-committal prayer, but the manner of its transmission savours a little of blackmail. It would be interesting to know whether such prayers are peculiar to times of national calamity such as those of war or epidemics. A cumulative prayer might certainly have been employed by the pious as a prophylactic during the diffusion of, say, the Black Death. But at present we can find no instance of such.

THE LEPROSY PROBLEM IN THE UNITED STATES.

THE August number of the *Ohio State Board of Health Monthly Bulletin* contains an editorial on leprosy in which reference is made to the reported occurrence of several cases in that State during recent years. The writer of the article estimates that there are at the present time 3,000,000 lepers in the world, two-thirds of whom are Chinese and 200,000 live in India, the remainder being scattered irregularly throughout other countries in the eastern and western hemispheres. It is said that there are in the United States some 500 persons suffering from leprosy, Louisiana, California, New York, and Minnesota being the States especially involved. The precautions taken to prevent the spread of the disease are not uniform nor are they effective in all instances. Fears are expressed that if proper measures be not taken there will be a marked increase in the number of cases during the next few years. A Bill has been recently introduced into Congress for the establishment of a national asylum for leprosy, or "leprosarium," as it is termed in some American quarters, to be located in a situation selected by the Surgeon-General of the United States Public Health Service. The Bill, however, does not appear to have aroused much interest in the minds of the people's representatives, and fear is expressed that the measure may be shelved unless public attention is strongly directed to it by sanitary workers and medical practitioners. As leprosy may become a real problem to be faced in the near future by the American people, now would appear to be the time to attack it. The passage of the Bill through Congress should facilitate the safe disposal of a menace to the inhabitants of the United States.

ASTEREOGNOSIS AND DEJERINE'S ROOT SYNDROME.

THE later work of several French neurologists, especially Dejerine, has emphasised the clinical significance of loss or diminution of form perception. The term agnosia, perhaps, is better, as this more aptly limits the sense of stereognosis to inability to recognise objects because of lack of information about them, and excludes the factor of judgment. The factors responsible for astereognosis are mainly deficient tactile and deep sensibility—depression, that is to say, of the two main sensory channels of information to the brain. It is usually necessary for both these senses to be depressed; deep sensibility alone may induce agnosia. Additional causes of agnosia may be found in certain forms of cerebral hemianæsthesia; in a few cases where a lesion damages the bulb, and especially when a lesion exists just behind the ascending parietal convolution (Wernicke, Milles, and Weisenburg). Finally, there are cases of agnosia due to insufficient education of stereognosis, such as occurs in infantile hemiplegia or brachial monoplegia (Pélissier and Regnard). The practical value of astereognosis has lately been especially emphasised by Dejerine in that its detection, indicative of depression of deep sensibility, facilitates the diagnosis of a new syndrome, termed by him the "syndrome of the long root fibres of the posterior column." Such a syndrome presents some resemblances to tabes dorsalis; it reveals, however, important and significant differences which have a definite anatomical basis. In this syndrome there may be ataxia of the limbs, but the sensibility is different from that of tabes. In tabes both deep and superficial sensibility are depressed; in Dejerine's syndrome deep sensibility is markedly depressed, as evidenced by agnosia, but tactile sensation is normal. The explanation of this difference is this. Tabes is essentially a posterior root lesion, and as such damages the transmission of all forms of sensory impulses, not only those of superficial sensation, touch, pain, and temperature, which pass into the cord by short and medium length fibres, masking rapidly in this way the posterior horn cells, but it also injures the long fibres of the sensory tract, which convey deep sensations and which do not immediately mask the horn cells. In Dejerine's syndrome, on the other hand, since superficial sensibility is preserved, it is suggested, with the support, in one instance, of pathological examination, that the long root fibres are alone implicated. The etiology, consequently, is different in the two conditions. Dejerine's syndrome is not of syphilitic origin; it is rather a combined sclerosis of the cord of subacute type, and may follow acute infections or blood diseases. Since its first description by Dejerine other cases have been reported (Souques, Jumentié), and its clinical recognition may not be without significance in relation to its rational treatment.

A COLLEGE OF AMBULANCE.

A VALUABLE development of amateur ambulance and "first aid" work has taken place in England in the last two years, but it is doubtful if the country realises how much it owes to Mr. James Cantlie in this matter. That debt has, however, been well acknowledged by the real workers in this movement. At a recent meeting held at the Polytechnic, Regent-street, W., it was proposed to establish in Mr. Cantlie's name a College of Ambulance, at which a more systematised and special instruction may be given in such work than is at present available. By the generosity of Mr. James Boyton, M.P., the college is to be housed in Vere-street in a satisfactory manner. The equipment of the college will include a museum of apparatus and models of contrivances employed in modern scientific ambulance work. Demonstrations and classes are to be systematically given on subjects chosen from time to time, and courses of instruction will be held for medical officers, commandants, and other officers engaged in this service. It is further proposed to institute diplomas in this subject and to affiliate the examinations of the various existing bodies. The proposal will meet with a ready welcome from all those engaged in ambulance work. We do not welcome with any particular favour the creation of diplomas in special subjects allied to medicine, but if they will be useful in raising the standard of "first aid" work we have nothing to say. The more enthusiastic these workers are, the more they will feel the limitations of their own knowledge and the lack of a higher plane of instruction, while the institution of a hall-mark will show that such lack is being supplied. But the improvement of the scientific aspect of first aid to the injured is not the whole matter presented to the minds of Mr. Cantlie and his friends. They seek to embody with that improvement the formation of a "humanitarian corps" to render first aid to those in need; to revive in a material age a successor to the two well-known bodies which both had origin from plague and pestilence, the Parabolani of the Alexandria of the reign of Gallienus and the Frati della Misericordia of Florence of the thirteenth century.

HUNTERIAN SOCIETY.—The session of the Hunterian Society will open on Wednesday, Oct. 14th, when Sir Dyce Duckworth will deliver the first Hunterian Society lecture on the Patient and the Disease, at 9 P.M. The meeting will take place at the hall of the Worshipful Company of Barbers, Monkwell-street, E.C. All members of the medical profession are invited to attend.

THE MANCHESTER RADIUM COMMITTEE.—In spite of many other matters that require attention in this unwonted period of activity the radium question in Manchester is being kept well in view. The Radium Committee, which raised about £31,000 for the purchase of radium, have secured a large supply which was intended for German hospitals. From Pittsburg radium to the value of £15,000 has been ordered and will be delivered in a few days. The new radium department at the Royal Infirmary will be opened at the beginning of November.

A NOTE UPON THE WOUNDS OF THE PRESENT CAMPAIGN.

BY G. H. MAKINS, C.B., F.R.C.S. ENG.,
CONSULTING SURGEON TO THE FORCES.

PERHAPS no greater surprise has been experienced than the nature of the wounds met with in the present war. The relative frequency of wounds from bullets of small calibre and those inflicted by shrapnel or fragments of shells which was observed in the South African war has been actually reversed. Moreover, of the limited number of bullet wounds a considerable portion have been inflicted by machine guns of the Maxim type and not by rifles.

A survey of the serious wounds in any hospital forcibly reminds the observer of the water-colour drawings made by Sir Charles Bell, and preserved at the Royal Army Medical College, and he seems transported to the era of the Peninsular war or of the Crimea. There is, in fact, little difference between wounds inflicted by the German shrapnel and those of the round ball fired from the old-fashioned musket.

Recent experience as to the course taken by bullet and shell wounds respectively has been fully confirmed. Wounds produced by the small calibre bullet maintain an aseptic condition if uncomplicated, while shrapnel and shell wounds without exception become infected and suppurate. The mere occurrence of suppuration in the case of even extensive wounds of the soft parts has led to less serious consequences than might have been expected; the sloughy surfaces rapidly clean up, especially under the influence of an iodine bath (ʒi. to the Oi.), and the patients, after a couple of days' rest in bed, show wonderfully little sign of constitutional infection. This is also the case in many of the compound fractures, although it is difficult to gauge how long and tedious their course to ultimate recovery may prove.

Nature of the Wounds.

The nature of the rifle wounds differs little, if at all, from that observed in the case of the Lee-Metford or dome-shaped Mauser bullet, except that the openings are of slightly larger size. The comparative infrequency of bullet wounds accounts for the fact that isolated nerve and vascular injuries are not common.

The wounds produced by the shrapnel balls vary in importance with the velocity retained at the moment of impact; some merely bruise, while others penetrate, and others, again, produce injuries of the most severe "explosive type." The entry wounds are comparatively small, often of the slit or gutter type, while the exit, especially where the bones are near the surface, as in the forearm or leg, may be a large mass of extruded lacerated muscle with numerous fragments of the comminuted bone exposed upon the surface. Such wounds are undoubtedly far more common than was the case in South Africa, and although some may be due to rifle bullets, the men themselves are confident they were produced by shrapnel. The patients also attribute extensive lacerations of the soft parts without injury to the bones to shrapnel bullets, but it seems obvious that these have been caused by fragments of the case or of high explosive shells. Such fragments penetrate, sometimes leaving a narrow bridge of skin over an extensive laceration of the subjacent soft parts. When they strike the bones a deep wedge-shaped groove is cut, numerous fragments of the bone adhering to the soft parts, while the extremities of the cut bone sometimes present the appearance of a fracture of cane, actual threads of bone projecting into the wound. Lodgment both of bullets and shrapnel balls is comparatively common, and contour wounds of the chest and head are not rare.

Certain special characteristics due to the use of machine guns and shrapnel are very striking. Thus a man struck by a machine gun may have a line of wounds passing from right to left across the body; in one case five separate wounds at the same level were distributed across the chest. Again, when exposed to shrapnel fire, where the shell bursts low, a very large number of balls may strike the same individual; as many as 34 wounds of varying severity have been counted on the body of one man. In spite of the fact that no separate wound is of any severity, such multiple wounds cause extreme shock, from which many of the patients die, while others take some days before reaction is complete.

The vast majority of the wounds do well, the bullet wounds of the soft parts taking the same uneventful course already familiar. In the more serious injuries due to shrapnel or fragments of shells, a few days' rest usually suffices to reinvigorate the patients; there is little evidence of constitutional infection either in the general appearance, the temperature, or the pulse-rate, and the men eat, drink, and sleep well. It is also very remarkable how little the majority of the men are affected psychically by the grave conditions, both bodily and mental, to which they have been exposed for some weeks.

Wound Complications.

Suppuration and a variable amount of sloughing of the soft parts are the rule. After a few days the most striking feature is the rigid eversion of the skin margin of the wound which persists for some time. When the wound is a deep circular one the resemblance to a crater in a malignant growth is very great, but in a short time the edge softens and flattens down, the wound itself then becoming covered with large masses of soft granulations which bleed freely.

In a certain proportion of cases the result is more serious, especially in men who have lain out a long time and suffered during transport. A spreading gaseous cellulitis develops which rapidly extends the whole length of the limb to the trunk. The parts above and below become rapidly involved by a soft doughy œdema first evident along the line of the main lymphatic trunks, and spreading eventually through the entire thickness of the limb. The tissues are often crepitant, and a dark reddish discolouration appears over the dependent parts. Meanwhile abundant sanious pus and bubbles of very stinking gas escape from the wound itself. The white tense limb with marbling on the surface characteristic of infections with bacillus aerogenes capsulatus I have not seen. The bacteriology of these wounds is now being worked out. The resulting gangrene is difficult to treat by amputation, as the flaps rapidly assume the condition of the gangrenous part removed. When temporised with the gangrene shows a tendency to localise itself, mummification commences, and if free enough exit for the discharge can be provided a chance of a later operation is gained. Gangrene of this character is responsible for a very considerable mortality.

Tetanus: Prophylactic Use of Serum.

A very serious complication of wounds is the development of acute tetanus, running a very rapid course, but not marked by very severe spasms. This as a rule develops during the first week after the reception of the wound, but sometimes as late as the tenth or fifteenth day. The initial source of infection is to be traced to the soil; it has been suggested that the trucks forming the ambulance trains and straw used for bedding down the patients might be responsible, but for this no evidence exists, and many patients have developed the disease prior to transport. The scourge is affecting the armies of the Allies and Germany in equal degree of severity. An attempt to control its development by the administration of prophylactic doses of serum to all patients with severe open wounds as soon as they are brought in from the field is now being made.

There is no doubt that these complications are the direct result of difficulties of collection and transport of wounded attendant upon the military conditions under which fighting is now taking place. Many of the patients lie in the trenches until the darkness of night allows of their removal; their clothes are infiltrated with mud, while the same shell which has caused the wound often brings down the side of the trench and the injured limb may be covered with soil. Again, the fragment of shell itself is commonly fouled with soil. Abundant opportunity thus exists for a primary infection of the wound of a very gross nature by the organisms of the soil. One has only to look over the neighbouring fields to appreciate the amount of manure with which the soil is treated, since the agriculturists are now placing the manure on the fields behind the fighting line prior to ploughing it in. One may well look back with envy to the clean soil of the South African veld, much as the dust was then regarded as a bugbear.

Wounds of Head, Face, and other Parts.

A large majority of the wounds of the head are the result of injuries caused by shrapnel balls. The German shrapnel is a little smaller in calibre than our own, and cast of lead apparently hardened by some alloy; the tangential wounds are often wide grooves in the scalp with considerable comminution of the bones. When striking directly the ball rarely passes deeply, often lying on the dura, or if it perforates the latter not passing deeply into the brain. Some of the tangential wounds are accompanied by very extensive brain laceration. The fact that most of the wounds are infected before the patients reach the hospital renders them unfavourable cases to deal with at once, but the local conditions as a rule rapidly improve, and then later operations can be undertaken. Wounds of the face and jaws are very common, also extensive injuries of the palate. Shrapnel balls pass through the cheek by comparatively small openings, often of the slit form, while the alveolus or palate may be widely damaged. No special features are presented by the chest injuries, beyond the fact that they are generally more severe than those seen in South Africa, and I think the association of spinal complications without evidence of the ball having actually traversed the vertebral column is more common. A small proportion of perforating wounds of the abdomen which have been accompanied by no untoward symptoms are seen in most of the hospitals. In all these cases the injury has been caused by rifle bullets. Shell wounds of the sacral region are not uncommon and are very distressing; in some the spinal canal is laid open, others are complicated by incontinence of fæces. It is a suggestive fact that few similar injuries of the anterior wall of the abdomen come into hospital, although an occasional lacerated wound with hernia of the omentum has been seen.

The rarity of division of individual nerves and large blood-vessels has been already remarked upon. After passing through more than a dozen large hospitals I have only seen two false aneurysms, one an arterial hæmatoma of the femoral, and one arterio-venous injury of the posterior tibial vessels. Fractures are numerous and severe, accompanied by large wounds and much comminution, while injuries to the joints are of a gross nature and almost without exception complicated by fracture of the articular ends of the bones.

Transport Difficulties.

The difficulties attendant on the transport and treatment of the very large number of wounded have been in themselves immense, and have been further enormously aggravated by the complications dependent on the early backward movement of the troops. Happily the period of more leisurely advance has allowed the establishment of a large number of hospitals in suitable positions, and the heavy task which has devolved upon the medical service of the army is in some measure eased. The problem has been faced with energy and devotion by all concerned, and unfortunately death has exacted a heavy toll on the medical officers employed with the advanced troops.

THE BRITISH PHARMACOPŒIA, 1914, FROM THE PHARMACEUTICAL POINT OF VIEW.

JUDGED from the pharmaceutical point of view the new Pharmacopœia stands on a much higher level than its immediate predecessor. This was to be expected, in view of the fact that during the 16 years that have gone by since the last edition was published much progress has been made in the science of pharmacy; improved processes for determining the precise quantitative composition of drugs have been devised, as well as more accurate methods for detecting the presence of impurities, while in the manufacturing laboratory much has been achieved that is usefully reflected in the new Pharmacopœia. To those who are not quite so familiar with the 1898 edition as they should be the new work will, perhaps, at first sight, seem to differ in a not very important degree from the one it supersedes, but a careful comparison of the two volumes dispels this impression.

Changes in the New Pharmacopœia.

On every page and practically in every monograph changes—some of them based on rational grounds, some rather subtle—have been introduced, and there is hardly a pharmaceutical or analytical process that has not been revised, if not fundamentally changed. The most noticeable alteration, but not the most important, is the discarding of the imperial system of weights and measures in the working directions to pharmacists and analysts. In the last edition both the imperial and the metric systems were employed for computations, and if the opinions of pharmacists were asked it would no doubt be found that in 99 cases out of 100 the metric figures were never used. Presumably the General Medical Council had sufficient reasons for enforcing this change in pharmaceutical practice, but it is not likely to be popular with the older school of chemists, who would have preferred to be allowed a privilege similar to that which has been accorded to medical practitioners for whose benefit doses are stated in both systems. Indisputably, there are sound reasons why the metric system should alone be used in medicine and pharmacy, but the transitional period might possibly have been prolonged a little. Presumably the Council foresee that in the edition which will supersede the Pharmacopœia of 1914 even doses will be given solely in the metric system, and it might therefore be wise for prescribers gradually to accustom themselves to thinking in grammes and centigrams and mils and decimils; "mils," by the way, is the short designation for millimetres—and a common-sense one too.

It is noted in the valuable preface to the work supplied by the Pharmacopœia Committee of the General Medical Council that the "doses" mentioned in the Pharmacopœia are not authoritatively enjoined by the General Medical Council as binding upon prescribers. This has always been understood, but it is just as well that it should be made the subject of an official statement; and incidentally it may be pointed out that medical practitioners would save dispensers from many a perplexity if in ordering unusually large doses they made it clear in some way or other that the large dose was intended, otherwise the doubt might arise as to whether it was due to a slip of the pen. Those practitioners who intend to prescribe in terms of the metric system will, of course, cease to employ the symbols for ounce and drachm; but it will be interesting to observe how many of those who persist in using the imperial system will adopt the recommendation given in the preface that they should cease to employ these symbols in any case. The reasons for these recommendations are sound enough ("the symbol ʒj is often used to represent 60 grains and also to represent the fluid drachm, and the symbol ℥j to represent 480 grains, sometimes 437·5 grains, and also to represent the fluid ounce"), but the use of these symbols has been so long interwoven into the art of prescription writing that it is probable that custom will prevail.

Drugs and Preparations Omitted or Added.

Of the 168 drugs and preparations that have been discarded from the Pharmacopœia and Addendum the majority are rarely prescribed, if not almost obsolete. There are a few, however, which are still in frequent use, but the reasons for leaving them out of the official book of medicines are no doubt well founded. Among the better known drugs that have disappeared from the Pharmacopœia the most noticeable is perhaps sarsaparilla; but this root has long been considered to be useless. Gamboge is admittedly too drastic and uncertain; cantharides has been left out, but replaced by its active principle; mustard, figs, hops, and prunes are commercial products needing no definition; jaborandi is left out, but its active principle remains, and the same applies to pomegranate root bark and coca leaves; dandelion extract is commonly regarded as useless, while musk, although largely used for other purposes, is now seldom prescribed as a medicine. Most of the omissions are, in fact, capable of some simple explanation, but it is not easy to suggest reasons for the discarding of several of the drugs in the long list of deletions—for instance, elder flower water, which is commonly prescribed in eye lotions. The fewness of the additions, however, is more surprising than the length of the list of exclusions. Only 43 drugs and preparations have been introduced, which is about half the number added in 1898. Never in any corresponding length of time in the whole history of medicine have so many new drugs come into use as during the period that has elapsed since the last Pharmacopœia was published. There has been a constant flood of new remedies; hundreds, if not thousands, of them have enjoyed at least a passing vogue, and yet the new Pharmacopœia contains less than a dozen of them, for only a small proportion of the additions come within the category of new remedies. The best known of the substances that have justified their claim for a place are adrenalin, acetylsalicylic acid, diethyl-barbituric acid, chloral formamide, diamorphine hydrochloride, ethyl chloride, hexamethylene-tetramine, methylsalicylate, methylsulphonal, phenolphthalein, benzamine lactate, resorcin, senna pods, and strontium bromide. The desirability of fixing official standards for these commonly prescribed drugs is obvious. The short name adopted for diethyl-barbituric acid (which was first introduced into medicine under the proprietary title of veronal) is barbitone—a good name and one easily remembered; for acetylsalicylic acid no short synonym is given, but the name hexamina for hexamethylene-tretramine will be found useful by prescribers. Diamorphine chloride is more familiar under the short trade-mark name of heroin, while benzamine lactate is more familiar as β eucaine, and methylsulphonal as trional.

Alterations in Strengths of Preparations, &c.

Of equal importance to the lists of omissions and additions are the alterations that have been made in the strengths of some 40 of the official preparations. In many instances these changes have been necessitated by the decision of the General Medical Council to adopt most of the recommendations of the International Conference on the Unification of the Formulæ of Potent Drugs and Preparations. It is essential that medical practitioners should carefully examine the changes in the strength of such galenical preparations as the tinctures of aconite, belladonna, colchicum, digitalis, nux vomica, opium, and strophanthus. In prescribing these tinctures it must be borne in mind that the difference between the potency of the preparations of the Pharmacopœia of 1914 and that of 1898 are considerable. Thus, the new tincture of strophanthus is four times the strength of the old; the new tincture of opium is 33 per cent. stronger than the old; while the new tincture of nux vomica is half the strength of the old; and in the strengths of all the potent tinctures there are changes of at least minor importance. The modifications in the names of some 38 substances do not constitute a very important feature of the new work, while the alterations in the directions for the preparation of some 50 compounds interest the manufacturing chemist rather than the medical practitioner or the pharmacist. The fixing of limits to the proportion of lead and arsenic permissibly present as impurities in some 90 pharmaceutical substances is a step that has long been advocated by chemists, and it is satisfactory to note that this step has been taken.

The number of crude drugs and of their galenical preparations which are required to contain a definite proportion of the chief active constituent or constituents has been increased. Thus, belladonna leaves are required to contain not less than 0·3 per cent. of alkaloids; nux vomica is adjusted to contain 1·25 per cent. of strychnine, as that alkaloid is practically the only toxic alkaloid present, brucine being much less important from the medicinal point of view; aconite root must contain not less than 0·4 per cent. of ether soluble alkaloids; and most of the potent drugs and preparations are standardised where possible. With the object apparently of encouraging uniformity in the writing of prescriptions abbreviations of Latin titles of drugs and preparations have been adopted in the Index. It is true that some of the abbreviated names—such, for instance, as acac. cort. (for acaciæ cortex), acid. bor. (for acidum boricum), scill. (for scilla), and trag. (for tragacantha)—are not elegant, but if the list is found useful to prescribers and dispensers it will serve its purpose. The monographs on the volatile oils and fixed oils bear evidence of very thorough revision.

The new Pharmacopœia is remarkable for the changes that have been made with the object of rendering it more precise, and a careful examination of the volume yields convincing evidence that an immense amount of work has been accomplished by the committee of reference in pharmacy, whose valuable help has been acknowledged in the preface.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeon: E. C. Sawdy to the *Vivid*, additional, for disposal. Surgeons: R. A. Brown to the *Audacious*, temporarily; and R. M. Riggall to the *Pembroke*, for Royal Naval Barracks. Temporary Surgeons: F. Nunneley to the *Dreadnought;* and G. P. O'Donnell to the *Vivid*, additional, for Devonport Dockyard.

Surgeon Probationers for temporary service: S. R. Prall, J. A. D. Skinner, A. F. G. Guinness, J. M. Harrison, E. D. Brooter, R. N. Craig, M. H. K. Kane, A. G. Lennon-Browne, E. A. Holmes, S. E. Y. Elliott, H. G. Stormer, W. B. Heywood-Waddington, G. F. Cobb, L. S. Fry, F. G. Tweedie-Lewtas, R. H. Clarke, W. G. S. Neely, C. Y. Roberts, S. J. L. Lindeman, G. E. Heath, R. G. Morgan, and H. W. L. Molesworth.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon: J. K. Murphy promoted to Staff-Surgeon, with seniority of Sept. 25th.

Temporary commissions in the Royal Naval Volunteer Reserve have been issued as follows:—To be Surgeon: Arthur Craigie McVittie and William Andrew Mallam (dated Oct. 3rd).

The undermentioned has been appointed Surgeon: William James Aitken Quine (dated Oct. 4th).

ARMY MEDICAL SERVICE.

The undermentioned to be temporary Colonels:—Dated Sept. 16th: Lieutenant-Colonel George H. Makins, C.B., 2nd London (City of London) General Hospital, Royal Army Medical Corps, Territorial Force; and Lieutenant-Colonel Sir Anthony A. Bowlby, C.M.G., 1st London (City of London) General Hospital, Royal Army Medical Corps, Territorial Force.

ROYAL ARMY MEDICAL CORPS.

Supernumerary Captain Archer Irvine-Fortescue, from the seconded list, is restored to the establishment (dated Sept. 25th). Frederick F. Bond, St. John Ambulance Brigade, Bearer Companies, to be temporary Captain (dated Sept. 25th).

The undermentioned officers, Home Hospitals Reserve, to be temporary Captains:—Dated August 6th: A. M. Wood, A. G. Price, G. W. Simla Paterson, J. G. McColl, W. L. Lyall, A. T. Campbell, W. W. Fyfe, J. A. Gray, R. J. Johnston, and G. Melville. Dated August 8th: W. C. Stevenson. Dated August 12th: C. T. W. Hirsch. Dated August 14th: W. F. Croll. Dated August 25th: J. M. Young.

The undermentioned to be temporary Lieutenants:—Dated Sept. 26th: David Hamilton Hadden, John Aquila MacMahon, Douglas Wardleworth, Kenneth Chisolm Middlemiss, Charles Lovell Spackman, Robert William Lang Todd, Morton Peto, William Brown, Francis Wardlaw Milne, Charles Walter Gordon Bryan, and Allan Noel Minns. Dated Sept. 28th: Maurice Fitzmaurice-Kelly and James Leslie Ruthven Philip. Dated Sept. 30th: Frederick Bernardus Dreyer.

Special Reserve of Officers.

Royal Army Medical Corps.

The undermentioned Cadets and ex-Cadets of the Officers Training Corps to be Lieutenants (on probation):—Eric Catford, William Oliver Lodge, Cyril Jacobs, Gordon Alexander Hodgson, Samuel Drummond Greer McEntire, Gerald Graham Alderson, Pensam Thornton, Bryan Montague Tuke, Alfred Percy Smith, James Calvert Spence, and John Edwin Allan.

The undermentioned to be Lieutenants (on probation):—John Percy Litt, John Paulley, Richard Pitt Ballard, William Wood Shorten, Alexander Lawrence Robb, Robert Hay, John Cowan, Griffith Lewis Jones, William Hern Cornelius, Frank Sykes, Samuel Armstrong Lane, Leslie Herbert Worthy Williams, James Macallan, Kingsley Wassell Lewis, Charles Layton Balkwill, William Hopper Shephard, Herbert Smith, Robert Godfrey Martyn, Frederick Vivian Bevan-Brown, Cecil John Rogerson, Patrick Joseph Corcoran, William McCombie, Norman Cameron, John Revie Caldwell, Claude Joscelyn Delaberé May, William John Sivewright Ingram, Armando Dumas Child, Jeremiah John Magner, Hector Smith, John Alfred Ryle, and Kingsley Louis O'Sullivan.

Supplementary to Regular Units or Corps.—The undermentioned Cadets and ex-Cadets of the Officers Training Corps to be Lieutenants (on probation):—Arthur Joseph Beveridge, George Albert Clark, Carl Damien Newman, Norman Braithwaite, Charles Frederick Hacker, James Kenworthy Johnston Haworth, Laurence Heber Warneford Iredale, Frank Miller Rorie, Cedric Overton Shackleton, Gilbert Wolridge Rose, William Dinsdale Anderton, Roland Harris Graham, Charles Arthur Wilson Ramsay, George Marsden Roberts, James McKay, James York Moore, William Blacker Cathcart, Hugh Gregan Crawford, William Barry Postlethwaite, James Salmond Robinson, John Edward Foley, Robert Patrick Archibald Kirkland, William Leonard Eliot Reynolds, Grantly Dick Read, Arthur Frederick Isbell Patterson, and Gerald Patrick Kidd.

The undermentioned to be Lieutenants (on probation):—Thomas Copeland Storey, William Alexander MacLellan, George Henry Chavasse Mold, John Francis Hill, Gerald Conroy Dixon, Charles Frank Burton, John Newton McIntosh, Stuart Dewar Robertson, Richard Harold Hodges, Thomas Knowles Boney, George Frederick Clifton, Ernest Frederick Guy, Charles Harry Greville Penny, Thomas Whittle Martin, James Elliot Black, Edwin Cyril Widmerpoole Starling, John Stanley Cocks, Gerald Thomas Mullally, and Robert Cathcart Ozanne.

Territorial Force.

Royal Army Medical Corps.

1st Highland Field Ambulance: William Henry Eden Brand to be Lieutenant.

2nd Home Counties Field Ambulance: Captain William H. Flint to be Major.

3rd Northumberland Field Ambulance: Lieutenant George H. Watson, from Attached to Units other than Medical Units, to be Lieutenant.

Attached to Units other than Medical Units.—To be Captains: Lieutenant Dudley R. Harris and Lieutenant Frederick A. W. Drinkwater. To be Lieutenants: Charles Butler, William Leslie Burgess, and Frank Winter Lawson.

Journal of the Royal Army Medical Corps.

Among the contents of this journal for September is an article on the Bacteriological Examination of Waters in the Field, by Major P. S. Lelean, which will be read with particular interest at a time when a practical knowledge of the subject is so important. Major Lelean records the results which he obtained during a recent reconnaissance of the water sources in a manœuvre area when he visited 93 towns and villages and obtained data with regard to 289 samples of water. He clearly describes the equipment necessary for the work and the routine which he followed, and lays stress on the assistance which medical officers in charge of sanitary districts on the lines of communication would have by a knowledge of the normal bacterial content of the water-supplies of the camps. Major J. B. Anderson supplies some interesting notes on trooping season 1914–1915, and in the clinical department of the journal there is a description of a bacillus very closely related to B. typhosus which was isolated from a blood culture. The section of this journal devoted to travel is always interesting, and this month's "Glimpses in the Netherlands, 1913," by Colonel J. M. Beamish, with its brief descriptions of Bruges, Ghent, Amsterdam, Rotterdam, and The Hague, especially appeals to us at the present moment. God's Acre in North-West India, by Colonel R. H. Firth, is the first instalment of a record of the names, the careers, and details as to the graves of, or monuments to, all the medical officers buried or memorialised in the Punjab, the North-West Frontier Provinces, and Kashmir.

West African Medical Staff.

The deaths are announced of Dr. T. P. Fraser (killed in action) and Dr. J. A. Harley.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 9246 births and 5441 deaths were registered during the week ended Saturday, Sept. 26th. The annual rate of mortality in these towns, which had been 14·4, 15·2, and 15·1 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year, rose to 15·7 per 1000 in the week under notice. During the 12 weeks of the quarter the mean annual death-rate in these towns averaged 13·1, against 13·2 per 1000 in London. Among the several towns the death-rate in the week under notice ranged from 6·2 in Southend-on-Sea, 6·6 in Eastbourne, 6·7 in Bournemouth, 7·9 in Swindon, and 8·1 in Ealing, to 22·7 in Middlesbrough, 22·9 in South Shields, 23·2 in Liverpool, 23·8 in St. Helens, 31·0 in Gateshead, and 34·8 in Wigan.

The 5441 deaths from all causes were 182 above the number in the previous week, and included 1189 which were referred to the principal epidemic diseases, against numbers steadily increasing from 394 to 1437 in the 11 preceding weeks. Of these 1189 deaths, 1004 resulted from infantile diarrhœal diseases, 56 from diphtheria, 50 from measles, 40 from whooping-cough, 23 from scarlet fever, 16 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3·4, against 4·0 and 4·1 per 1000 in the two preceding weeks. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had steadily increased from 112 to 1223 in the 11 preceding weeks, fell to 1004 in the week under notice, of which 245 were registered in London, 106 in Liverpool, 47 in Birmingham, 46 in Manchester, 32 in Stoke-on-Trent, 29 in Newcastle-on-Tyne, and 21 in Sheffield and in Sunderland. The deaths referred to diphtheria, which had increased from 31 to 53 in the six preceding weeks, further rose to 56 in the week under notice, and included 18 in London, 4 in Leeds, and 2 each in Plymouth, Devonport, Birmingham, Liverpool, and Cardiff. The fatal cases of measles, which had declined from 111 to 64 in the six preceding weeks, further fell to 50; 24 deaths occurred in London, 5 in Oldham, and 3 in Liverpool. The deaths attributed to whooping-cough, which had been 69, 51, and 50 in the three preceding weeks, further declined to 40, and included 13 in London, 3 in Liverpool, and 3 in Leeds. The deaths referred to scarlet fever, which had been 25, 39, and 27 in the three preceding weeks, further fell to 23, of which 7 were recorded in Manchester, 5 in London, and 2 in Salford. The fatal cases of enteric fever, which had been 17, 16, and 20 in the three preceding weeks, fell to 16, and included 2 in Hull.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased from 3071 to 3669 in the five preceding weeks, had further increased to 3964 on Sept. 26th; 674 new cases were admitted during the week, against 548, 619, and 551 in the three preceding weeks. These hospitals also contained on the 26th 1259 cases of diphtheria, 55 of enteric fever, 32 of whooping-cough, and 18 of measles, but not one of small-pox. The 1343 deaths from all causes in London were 5 fewer than the number in the previous week, and corresponded to an annual death-rate of 15·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 128, 132, and 110 in the three preceding weeks, rose to 140 in the week under notice, and were 15 in excess of the number in the corresponding week of last year.

Of the 5441 deaths from all causes in the 97 towns, 173 resulted from various forms of violence, and 357 were the subject of coroners' inquests, while 1547 occurred in public institutions. The causes of 44, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Bristol, West Ham, Bradford, Hull, Portsmouth, and in 70 other smaller towns. Of the 44 uncertified causes of death, 9 were registered in Liverpool, 6 in Birmingham, 4 in Gateshead, 3 in London, 3 in Newcastle-on-Tyne, and 2 each in West Bromwich, St. Helens, and South Shields.

In the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8659 births and 4966 deaths were registered during the week ended Saturday, Oct. 3rd. The annual rate of mortality in these towns, which had been 15·2, 15·1, and 15·7 per 1000 of their aggregate population estimated at 18,120,059 persons at the middle of this year, declined to 14·3 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 13·2, against 13·3 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 3·0 in Dudley, 5·6 in Gillingham, 7·2 in Cambridge, 7·7 in Oxford, and 8·2 in Hornsey, to 21·2 in Tynemouth, 21·6 in Warrington, 21·8 in Great Yarmouth and in Wakefield, 22·0 in Stockton-on-Tees, and 22·3 in Birkenhead.

The 4966 deaths from all causes were 475 fewer than the number in the previous week, and included 877 which were referred to the principal epidemic diseases, against 1437 and 1189 in the two preceding weeks. Of these 877 deaths, 651 resulted from infantile diarrhœal diseases, 63 from diphtheria, 61 from measles, 50 from whooping-cough, 29 from scarlet fever, and 23 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·5, against 3·4 per 1000 in the previous week. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 1172, 1223, and 1004 in the three preceding weeks, further declined to 651 last week, of which 183 were registered in London, 60 in Liverpool, 30 in Manchester, 26 in Stoke-on-Trent, 19 in Birmingham, 17 in Hull, 15 in Sheffield, and 12 each in Newcastle-on-Tyne and St. Helens. The deaths referred to diphtheria, which had steadily increased from 31 to 56 in the seven preceding weeks, further rose to 63 last week, and included 19 in London, 6 in Stoke-on-Trent, 4 each in Birmingham and Middlesbrough, 3 in Leyton, and 2 each in West Ham, Portsmouth, Blackburn, and Leeds. The fatal cases of measles, which had declined from 111 to 50 in the seven preceding weeks, rose to 61 last week; 19 deaths were recorded in London, 5 each in Birmingham and Birkenhead, 4 in Leeds, and 3 in Liverpool. The deaths attributed to whooping-cough, which had fallen from 69 to 40 in the four preceding weeks, rose to 50 last week, and included 12 in London, 5 in Newcastle-on-Tyne, and 4 each in Nottingham and Liverpool. The deaths referred to scarlet fever, which had been 39, 27, and 23 in the three preceding weeks, rose to 29 last week; 5 deaths were recorded in London, 5 in Birmingham, 4 in Manchester, and 2 each in Tottenham, Smethwick, Preston, and Sheffield. The fatal cases of enteric fever, which had been 16, 20, and 16 in the three preceding weeks, rose to 23 last week, of which 4 each occurred in London and Hull, and 3 in South Shields.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased from 3071 to 3964 in the six preceding weeks, had further risen to 4196 on Saturday last; 640 new cases were admitted during the week, against 619, 551, and 674 in the three preceding weeks. These hospitals also contained on Saturday last 1307 cases of diphtheria, 61 of enteric fever, 34 of whooping-cough, and 26 of measles, but not one of small-pox. The 1291 deaths from all causes in London were 52 fewer than the number in the previous week, and corresponded to an annual death-rate of 14·9 per 1000. The deaths referred to diseases of the respiratory system, which had been 132, 110, and 140 in the three preceding weeks, rose to 157 in the week under notice, and were 23 in excess of the number in the corresponding week of last year.

Of the 4966 deaths from all causes in the 97 towns, 163 resulted from various forms of violence, and 330 were the subject of coroners' inquests, while 1498 occurred in public institutions. The causes of 36, or 0·7 per cent., of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Portsmouth, and in 70 other smaller towns. Of the 36 uncertified causes of death, 4 each were registered in Birmingham and Liverpool, 3 each in Rochdale and Gateshead, and 2 each in Nottingham, Bootle, St. Helens, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1157 births and 699 deaths were registered during the week ended Saturday, Sept. 19th. The annual rate of mortality in these towns, which had increased from 13·8 to 16·5 per 1000 in the five preceding weeks, declined to 15·9 per 1000 in the week under notice. During the first eleven weeks of the quarter the mean annual death-rate in these towns averaged 14·2, against 12·9 per 1000 in the 97 large English towns. Among the several towns the death-rate during the week ranged from 7·6 in Motherwell, 9·4 in Ayr, and 10·2 in Kirkcaldy, to 18·4 in Perth, 21·8 in Coatbridge, and 23·0 in Hamilton.

The 699 deaths from all causes were 28 fewer than the number in the previous week, and included 119 which were referred to the principal epidemic diseases, against numbers steadily increasing from 49 to 137 in the seven preceding weeks. Of these 119 deaths, 96 resulted from infantile diarrhœal diseases, 8 from whooping-cough, 6 from scarlet fever, 4 from diphtheria, 3 from enteric fever, and 2 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·7, against 4·1 per 1000 in the 97 large English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had steadily increased from 29 to 101 in the six preceding weeks, declined to 96, of which 54 were registered in Glasgow, 11 in Dundee, 10 in Edinburgh, 4 in Greenock, 4 in Hamilton, 3 in Coatbridge, and 3 in Kilmarnock. The deaths referred to whooping-cough, which had been 15, 16, and 16 in the three preceding weeks, fell to 8, and included 6 in Glasgow. The fatal cases of scarlet fever, which had been 8, 4, and 12 in the three preceding weeks, fell to 6, of which 4 occurred in Glasgow. The 4 deaths attributed to diphtheria were slightly below the average in the earlier weeks of the quarter, and comprised 2 each in Edinburgh and Aberdeen. The 3 deaths from enteric fever were equal to the average in the earlier weeks, and comprised 2 in Glasgow and 1 in Greenock. The 2 fatal cases of measles were registered in Glasgow,

The deaths referred to diseases of the respiratory system, which had been 70, 65, and 73 in the three preceding weeks, declined to 62 in the week under notice; 33 deaths were attributed to different forms of violence, against 30 and 23 in the two preceding weeks.

In the 16 largest Scotch towns 1124 births and 717 deaths were registered during the week ended Saturday, Sept. 26th. The annual rate of mortality in these towns, which had been 16·0, 16·5, and 15·9 per 1000 in the three preceding weeks, rose to 16·3 per 1000 in the week under notice. During the 12 weeks of the quarter the mean annual death-rate in these towns averaged 14·4, against 13·1 per 1000 in the large English towns. Among the several towns the death-rate in the week under notice ranged from 7·3 in Kilmarnock, 12·5 in Falkirk, and 12·6 in Motherwell and in Ayr, to 7·4 in Greenock, 17·7 in Glasgow, and 19·4 in Paisley.

The 717 deaths from all causes were 18 in excess of the number in the previous week, and included 128 which were referred to the principal epidemic diseases, against 137 and 119 in the two preceding weeks. Of these 128 deaths, 87 resulted from infantile diarrhœal diseases, 13 from whooping-cough, 12 from scarlet fever, 9 from diphtheria, 4 from enteric fever, and 3 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·9, against 3·4 per 1000 in the large English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 89, 101, and 96 in the three preceding weeks, further fell to 87 in the week under notice, of which 54 were registered in Glasgow, 9 in Edinburgh, 8 in Dundee, 5 in Greenock, and 3 in Motherwell. The deaths referred to whooping-cough, which had been 16, 16, and 8 in the three preceding weeks, rose to 13, and included 11 in Glasgow. The fatal cases of scarlet fever, which had been 4, 12, and 6 in the three preceding weeks, rose to 12, and included 5 in Glasgow, 3 in Aberdeen, and 2 in Edinburgh. The deaths attributed to diphtheria, which had been 8, 6, and 4 in the three preceding weeks, rose to 9, of which 5 were recorded in Aberdeen and 2 in Glasgow. The 4 deaths referred to enteric fever were slightly in excess of the average in the earlier weeks of the quarter, and comprised 2 in Glasgow, and 1 each in Aberdeen and Kilmarnock. The fatal cases of measles were recorded in Glasgow, Dundee, and Greenock.

The deaths referred to diseases of the respiratory system, which had been 65, 73, and 62 in the three preceding weeks, slightly rose to 64 in the week under notice; 20 deaths resulted from various forms of violence, against 23 and 33 in the two preceding weeks.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1110 births and 687 deaths were registered during the week ended Saturday, Oct. 3rd. The annual rate of mortality in these towns, which had been 16·5, 15·9, and 16·3 per 1000 in the three preceding weeks, declined to 15·6 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 14·4, against 13·2 per 1000 in the 97 large English towns. Among the several towns the death-rate during the week ranged from 10·8 in Hamilton, 13·8 in Edinburgh and in Perth, and 14·0 in Kirkcaldy, to 18·1 in Greenock, 18·2 in Coatbridge, and 19·8 in Dundee.

The 687 deaths from all causes were 30 fewer than the number in the previous week, and included 92 which were referred to the principal epidemic diseases, against 119 and 128 in the two preceding weeks. Of these 92 deaths, 52 resulted from infantile diarrhœal diseases, 13 from whooping-cough, 12 from scarlet fever, 9 from diphtheria, 4 from enteric fever, and 2 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·1, against 2·5 per 1000 in the 97 large English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 101, 96, and 87 in the three preceding weeks, further fell to 52 last week, of which 28 were registered in Glasgow, 9 in Edinburgh, 5 in Dundee, and 2 in Greenock. The deaths referred to whooping-cough, which had been 16, 8, and 13 in the three preceding weeks, were again 13 last week, and included 11 in Glasgow. The fatal cases of scarlet fever, which had been 12, 6, and 12 in the three preceding weeks, were again 12 last week; 3 deaths occurred in Glasgow, 3 in Aberdeen, and 2 in Dundee. The deaths attributed to diphtheria, which had been 6, 4, and 9 in the three preceding weeks, were again 9 last week, and included 4 in Aberdeen and 2 in Glasgow. The 4 deaths referred to enteric fever, of which 2 were recorded in Glasgow, were slightly in excess of the average in the earlier weeks of the quarter. The fatal cases of measles occurred in Glasgow and Aberdeen.

The deaths referred to diseases of the respiratory system, which had been 73, 62, and 64 in the three preceding weeks, rose to 71 in the week under notice; 27 deaths resulted from various forms of violence, against 33 and 20 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 598 births and 443 deaths were registered during the week ended Saturday, Sept. 26th. The annual rate of mortality in these towns, which had been 18·1, 17·0, and 19·9 per 1000 in the three preceding weeks, fell to 19·2 per 1000 in the week under notice. During the 12 weeks of the quarter the mean annual death-rate in these towns averaged 16·8, against corresponding rates of 13·1 and 14·4 per 1000 in the English and Scotch towns respectively. The annual death-rate in the week under notice was equal to 18·4 in Dublin (against 15·5 in London and 17·7 in Glasgow), 22·1 in Belfast, 22·4 in Cork, 22·8 in Londonderry, 23·0 in Limerick, and 17·1 in Waterford, while in the 21 smaller towns the mean death-rate was 21·7 per 1000.

The 443 deaths from all causes were 16 fewer than the number in the previous week, and included 92 which were referred to the principal epidemic diseases, against 89 and 97 in the two preceding weeks. Of these 92 deaths, 71 resulted from infantile diarrhœal diseases, 9 from whooping-cough, 5 from measles, 3 from diphtheria, and 2 each from enteric fever and scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 4·0, against corresponding rates of 3·4 and 2·9 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 74, 71, and 74 in the three preceding weeks, fell to 71 in the week under notice and included 44 in Belfast, 13 in Dublin, 4 each in Cork and Londonderry, and 3 in Newtownards. The deaths referred to whooping-cough, which had been 3, 7, and 4 in the three preceding weeks, rose to 9, and included 4 in Belfast and 3 in Cork. The 5 fatal cases of measles, of which 4 occurred in Belfast, were 3 below the average in the earlier weeks of the quarter. Of the 3 deaths attributed to diphtheria, 2 were recorded in Dublin and 1 in Tralee; the 2 fatal cases of scarlet fever occurred in Belfast, and those of enteric fever in Dublin and Belfast.

The deaths referred to diseases of the respiratory system, which had been 49, 35, and 50 in the three preceding weeks, rose to 56 in the week under notice. Of the 443 deaths from all causes, 123, or 28 per cent., occurred in public institutions, and 10 resulted from different forms of violence. The causes of 16, or 3·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 English towns the proportion of uncertified causes in the week under notice did not exceed 0·8 per cent.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 676 births and 401 deaths were registered during the week ended Saturday, Oct. 3rd. The annual rate of mortality in these towns, which had been 17·0, 19·9, and 19·2 per 1000 in the three preceding weeks, further fell to 17·3 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 16·9, against corresponding rates of 13·2 and 14·4 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 19·1 in Dublin (against 14·9 in London and 15·5 in Glasgow), 17·4 in Belfast, 14·3 in Cork, 14·0 in Londonderry, 16·2 in Limerick, and 17·1 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 13·5 per 1000.

The 401 deaths from all causes were 42 fewer than the number in the previous week, and included 53 which were referred to the principal epidemic diseases, against 97 and 92 in the two preceding weeks. Of these 53 deaths, 41 resulted from infantile diarrhœal diseases, 6 from whooping-cough, 2 from diphtheria, 2 from scarlet fever, and 2 from enteric fever, but not one from small-pox or from measles. The mean annual death-rate from these diseases was equal to 2·3, against 2·5 and 2·1 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 71, 74, and 71 in the three preceding weeks, further declined to 41 last week, and included 21 in Belfast, 11 in Dublin and 4 in Cork. The deaths referred to whooping-cough, which had been 7, 4, and 9 in the three preceding weeks, fell to 6 last week, of which 4 occurred in Belfast. The deaths from diphtheria were registered in Dublin and Bangor, those from scarlet fever in Belfast and Limerick, and those from enteric fever in Dublin and Belfast; the number was in each case slightly below the average in the earlier weeks of the quarter.

The deaths referred to diseases of the respiratory system, which had been 35, 50, and 56 in the three preceding weeks, further rose to 58 in the week under notice. Of the 401 deaths from all causes, 127, or 32 per cent., occurred in public institutions, and 7 resulted from different forms of violence. The causes of 21, or 5·2 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 English towns the proportion of uncertified causes last week did not exceed 0·7 per cent.

WAR AND THE DANGER FROM CHOLERA AND PLAGUE IN THE NEAR EAST.

(BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

FIVE of the great Powers of Europe (England, France, Russia, Germany, and Austria), one great Power in the Far East (Japan), and three of the smaller European Powers (Belgium, Serbia, and Montenegro) are now involved in war—a war that is already not only the most colossal but also the most deadly that the world has ever seen. Deadly, not only on account of the enormous death-dealing powers that science has put into the hands of modern armies, but also on account of the angry passions aroused—passions that have been embittered a thousandfold by the atrocities committed against humanity and civilisation by one of the principal combatants. And to these death-dealing forces disease will most assuredly be added sooner or later. The experience of the next few months will show how far modern military medicine and hygiene have succeeded in keeping under enteric fever, dysentery, diarrhœa, and the many other disorders that have ravaged armies in almost all former wars. That these diseases will prevail to some extent is inevitable. Should cholera or plague be added to them the results will be still more disastrous.

In my last letter (published in THE LANCET of August 1st, p. 337) I showed that cholera had already made its reappearance in Russia, and now a more serious extension of the disease there has to be reported. In Turkey cholera was admittedly present, in and near Adrianople and elsewhere, as late as May last, and there is reason to believe that cases of the disease have recently occurred in and near Constantinople without being reported by the authorities. In Austria and in Roumania cholera was prevalent to a considerable extent in 1913; it only disappeared from those countries towards the end of the year, and a fresh revival of the disease there is far from impossible. But while the risk of a serious extension of cholera in Europe owing to the war cannot be excluded, that risk may be regarded as very greatly diminished by the fact, upon which I have dwelt before, that the present cholera virus in Europe is one which appears to have lost to a great extent its primitive force and virulence, owing, no doubt, to the long period that has elapsed since it was introduced into Europe from the endemic home of cholera in India.

Plague is a disease that offers far less menace to fighting forces than does cholera. Even the pneumonic form of the disease is scarcely likely to sweep over an army in the field; but the possibility of the infection, both in its bubonic and its pneumonic form, being diffused widely as a result of the war, and especially of its attacking refugees herded together under insanitary conditions, cannot be wholly lost sight of. I have added, therefore, to the following brief summary of recent cholera prevalence in the Near East a survey of the various outbreaks of plague that have been recorded in the same part of the world during the past few months.

Cholera in Russia.

As stated in my last letter on this subject, a fatal case of cholera was seen at Kherson on July 9th; no further cases of the disease have been reported from here. But in the government of Podolia there has been a more extensive outbreak. It began on July 2nd (15th), and the districts of Yampol and Vinnitza seem to have been the most seriously affected. According to a bulletin issued in the *Official Messenger* of July 25th (August 8th), there had occurred up to that date in the Podolia government 303 cases of cholera with 115 deaths. Of these, 241 cases and 84 deaths had been registered in the Vinnitza district; 52 cases and 28 deaths in the Yampol district; 8 cases and 3 deaths in the Litinsk district; and 2 cases in that of Bratslav. A later bulletin, dated August 19th (Sept. 1st), states that only isolated and sporadic cases of cholera had been seen in the interval, and that cholera had completely disappeared from most of the infected places formerly mentioned. On the other hand, some cases of cholera had been seen in the Ouman district of the Kief government, but no fresh case had been reported for five days. It had been rumoured that cholera was present in Batoum and other Russian ports of the Black Sea, but this was officially denied by the Russian Government on Sept. 5th.

Rumoured Cholera in Turkey and the Mobilisation.

After the Great Powers declared war (or began it without a declaration) Turkey lost no time in mobilising practically the whole of her army. The mobilisation has been on a larger scale, more thorough, more virulent, if the expression may be permitted, than even that of two years ago, when this country was truly at war. No one has been spared; requisitions have been carried out ruthlessly, with little regard for the law on the subject, whether local or international. Some half million or more of men are now in barrack and camp on a war footing, mostly in Adrianople and in other places on the European side of the Bosphorus and Dardanelles. If but one half of the stories be true that are widely repeated respecting the lack of food, proper clothing, and other necessaries from which these troops suffer, the condition of the latter must be lamentable indeed. No doubt most of these stories are exaggerated, but it is certain that the men are for the most part very badly found in food and other necessaries, and should cholera appear among them it might well cause a serious epidemic. For some time past it has been persistently rumoured that cases of the disease have occurred, first at Eski-shehir, in Asia Minor, then at Tchamlidja, one of the hills near the capital overlooking the Bosphorus, and now in Constantinople itself. Officially, nothing is published as to the truth or untruth of these rumours, but when inquiries are made the reply is carefully worded to the effect that no cases of cholera have occurred "among the civil population."

Cholera (?) in Serbia.

A telegram to the press from Salonica, dated Sept. 13th stated that cholera was prevalent at Nisch, where "many cases have already been observed." This is, however, denied by a press agency telegram from Nisch itself, dated Sept. 19th, which states that not a single case of cholera has been seen there.

Plague in Beirût and the Lebanon.

A few sporadic cases of plague have been observed in or near Beirût since as long ago as October, 1913. On the 27th of that month the first recorded case was seen in a village called Keferchina, situated in the Lebanon, at a distance of two hours from the town of Beirût. The patient was a dock labourer, but no evidence has been furnished as to the source of the infection. A month later, on Nov. 26th, another case was reported, occurring in Beirût itself; the patient was a factory hand. On Dec. 8th a soldier in the Beirût garrison fell ill with the disease, and a second case among the troops occurred on the 13th. The diagnosis in all the cases in the town itself was confirmed bacteriologically. No further case was heard of until May 16th, 1914, when a pupil at the English boys' school was found to be suffering from plague; the boy died on the 17th. On June 16th yet another case was seen; the patient was a man aged 45, a merchant living in the centre of the town; in this, as also in the preceding case, there was bacteriological proof that the disease was plague. On July 6th a mild case was reported, occurring in the south-east quarter of the town; and this was followed by other cases on July 25th, on August 2nd, and on August 23rd.

Plague in Jaffa and Caiffa.

On May 30th a negro "hamal," or porter, a resident in Jaffa, was found to be suffering from plague, and on the same day the body of another negro was discovered, presenting the external appearances of having died from plague. There followed two more cases on June 4th, one on the 8th, one on the 9th, and one on the 26th, since when Jaffa appears to have been free from the disease. It is remarkable that all these seven cases occurred in negroes and all apparently in the same quarter of the town. The source of the infection was not traced. In most, if not all, of the cases there was bacteriological proof of the nature of the disease. On August 29th a suspected case of plague was reported from Caiffa, but its exact nature was never confirmed.

Plague in Tripoli (Syria).

Only a single case has been reported from Tripoli; it was first seen on June 14th, but the patient, a grocer, was then said to have been ill for seven days.

Plague and Cholera in Greece and in the Islands of the Ægean.

The uncertain political status of many islands of the Ægean has led, among other results, to considerable difficulty in obtaining definite information as to their sanitary state, in respect of the presence or absence of epidemic diseases. Rhodes and the islands of the Dodecanese are in Italian occupation; Chios, Mitylene, and others are in Greek occupation, and few remain definitely in Turkish possession. Rumours of the existence of plague in Chios began to be heard as long ago as May. It seems to have been a fact that four cases of the disease did occur then; but how many more (if any) followed has remained uncertain. Early in August plague was again stated—on no very certain authority—to be present in Chios and in Samos, but no figures were made known, and it was not wholly unsuspected that the report of the existence of the disease in those islands was made with a political rather than with a purely sanitary object. On August 30th the Turkish Legation in Athens telegraphed to the effect that 12 persons arriving at the Piræus from Chios and Mitylene had been found to be suffering from plague and had been isolated at the village of Daphne, near to the Piræus. The telegram added that many cases of the disease were still occurring in Chios and Mitylene; but there has been no confirmation of this from other sources. On Sept. 3rd the Turkish Vice-Consul in the island of Syra (in the Cyclades) reported that a case of plague had occurred there on the 2nd, and that the patient had died on the 3rd. Finally, on Sept. 12th the Turkish Consul-General at Salonika reported that seven cases of plague had been observed there, three of the patients being soldiers and the other four immigrants. No intimation of this outbreak has, however, yet been received from the Greek authorities. On August 5th the Turkish Consul-General at Janina reported that a suspected and fatal case of cholera had occurred there. No subsequent information has been received respecting this case.

Plague in Smyrna.

The first known case of plague in Smyrna seems to have been that of a police official charged with the supervision of dock labourers; he died on the night of July 15th–16th, after three days' illness. On Sept. 2nd another case was reported. The patient, a woman, had been ill since August 22nd, and there was some doubt as to the real nature of the case. Two more cases were reported on Sept. 7th, and the same day it was announced that a grain merchant, who had died on the 5th with uræmic symptoms, had died from plague.

Plague in Adalia.

On July 31st a case of plague was seen in Adalia, on the south coast of Asia Minor, where, it will be recalled, sporadic cases of the disease have occurred almost every summer for many years past.

Plague in Jeddah.

The first case of plague in this year's revival of the disease in Jeddah was seen on Feb. 2nd. Between that date and March 11th some six cases in all were reported—a strikingly small number as compared with other recrudescences of the disease here in recent years.

Plague in Basra and on the Tigris.

On May 25th a case of plague was observed in Basra, the patient being a grocer. The following day three fresh cases were admitted to the American hospital (situated on the canal which joins the town of Basra to the great Shatt-ul-Arab river). These were followed by several other cases, and between the date named and July 17th 20 cases, with 12 deaths, were recorded. It may be added that one of these cases occurred on the premises of the principal

British navigation company in those waters, and that several dead rats were found on these same premises. On June 23rd the dead body of a passenger on one of the river boats that ply between Basra and Bagdad was landed at Kut-el-Amara, one of the principal places of call of these steamers, three days' voyage from Basra (on the upward journey). Fortunately there was no spread of the disease in Kut-el-Amara or elsewhere.

Plague in the Russian Steppes.

Since my last letter on this subject[1] the following have been the principal outbreaks of plague in the Kirghiz and Kalmuck steppes of Southern Russia. In the autumn of last year plague was present in four places in the Don Territory. At Novopetrovsk 35 cases with 34 deaths occurred between Oct. 7th and 28th; at a farm at Kalatch 5 cases with 4 deaths were seen between Oct. 11th and 28th; at Breslavsk also 5 cases with 4 deaths occurred between Oct. 16th and 29th; and at Gromoslavsk a few cases also occurred about the same time. On the other hand, an official notice of Nov. 9th stated that in all 58 cases of plague, all of the pulmonary variety and all fatal, had been registered in the Don Territory between Oct. 9th and Nov. 4th. Two medical assistants, named Kurilkin and Serpokarylof, died from the disease in this province. A severer outbreak occurred in the Uralsk province in November. Between the 2nd and 30th of that month 319 cases of the disease and 290 deaths were recorded, and at the last-named date 19 were still under treatment. This outbreak occurred mainly at Inder, in the district of Lbishtchensk, but there were also cases at Kalmykof, Kizildjar, and Djaksibaief. There was a revival of the disease at Inder in March of this year, when, between the 15th and 29th of the month, 16 cases of plague, all fatal and mostly of the pulmonary form, were recorded. In the Astrakhan government three cases of plague were seen at Aktubé at the end of December last. In the past summer several other centres became infected. Cases of the disease were seen at Boulanai, Manish-Tchagyl, Bektass-Tchagyl, and Tourgun, in the Kirghiz steppes of this government; at Arkhanskoé-Tebé, Kekshin, and Goubia, in the Kalmuck steppes; and in the village of Tsaref (all in the Astrakhan government). The total number of cases of plague here, between May 25th and July 16th, was 48, and 45 of these were fatal. (All the dates mentioned above are according to the New Style.) Between the last-named date and July 23rd no fresh cases were seen in this government. At Arkhanskoé-Tebé a member of the medical staff, Dr. Yefimof, caught the disease in its pulmonary form from a patient and died from it.

Constantinople, Sept. 19th.

---

[1] THE LANCET, Nov. 29th, 1913.

A MEETING of the Society for the Study of Inebriety will take place next Tuesday, Oct. 13th, at 4 P.M., when a discussion on Drug Addiction in Relation to Mental Disorder will be opened by Dr. Robert Armstrong-Jones.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—The following Entrance Scholarships and Exhibitions have been awarded in the Faculty of Medical Sciences:—Bucknill Scholarship (135 guineas), B. Rosenstein, of Westminster City School. First Medical Exhibition (55 guineas), H. N. F. Cook, of University College, London. Second Medical Exhibition (55 guineas), A. W. Holgate, of Alleyn's School, Dulwich. Proxime accessit, M. Baranov, of King Edward VII. School, Johannesburg, and University College, London. Epsom Free Medical Scholarship, H. E. Beasley.

DONATIONS AND BEQUESTS.—The late Mr. John Railton, of Alderley Edge, Cheshire, has left £1000 to the Manchester Royal Infirmary, Dispensary, and Asylum; £500 to the Manchester Royal Eye Hospital; and £500 to the St. Mary's Hospitals, Manchester, which include St. Mary's Hospital and the Manchester and Salford Lying-in Hospital, the Manchester Southern Hospital for Women and Children, and the Manchester Maternity Hospital.—The Royal Berkshire Hospital will receive £300 under the will of the late Mrs. Elizabeth S. Neall.—Under the will of the late Dr. Aldis Wright, LL.D., the Beccles Hospital will receive £500. The testator also left £5000 and his books to Trinity College, Cambridge.

Obituary.

SIR HENRY DUNCAN LITTLEJOHN, M.D. EDIN., F.R.C.S. EDIN., LL.D. EDIN. (HON. CAUSÂ),

LATE PROFESSOR OF FORENSIC MEDICINE, EDINBURGH UNIVERSITY;
EX-PRESIDENT, ROYAL COLLEGE OF SURGEONS, EDINBURGH;
AND MEDICAL OFFICER OF HEALTH OF EDINBURGH.

Sir Henry Duncan Littlejohn died at his country residence, Benreoch, Arrochar, N.B., on Sept. 30th, at the age of 86. He had been in poor health for the preceding three years, and this, together with his ripe age, rendered his death, though deeply regretted by many friends, the community at large, and his profession in particular, hardly unexpected.

Henry Duncan Littlejohn, who was the son of Thomas Littlejohn, a well-to-do merchant and burgess of Edinburgh, was born in that city in 1828. He received his general education at Perth Academy, and subsequently at the Edinburgh High School, whence he entered the University of Edinburgh. He graduated there as M.D. in 1847, and in the same year became a Licentiate of the Royal College of Surgeons of Edinburgh at the extra-mural school of which he received part of his medical education. He was admitted to the Fellowship in 1854. He studied for a while at the Sorbonne, in Paris, and also at the Universities of Vienna and Berlin. In 1855 he was appointed lecturer on medical jurisprudence at the Royal College of Surgeons, which post he continued to hold for 42 years, until, in fact, on the death of Sir Douglas Maclagan, he succeeded him in the corresponding professorship at the University of Edinburgh, being then in his sixty-ninth year.

In September, 1862, Sir Henry Littlejohn was appointed medical officer of health of Edinburgh, and it was in this capacity that he first set out on the road to distinction. Edinburgh was about that time a hotbed of epidemic fever, and he prepared a monumental report on the sanitary condition of the city, which dealt in an illuminating manner with the overcrowding, the filthy condition of the closes and houses, especially in the old town, the condition of the byres and bakehouses, the drainage, the water-supply, and so forth. His observations bore fruit (being reinforced in 1866 by another outbreak of cholera) in the passing of the Edinburgh City Improvement Act of 1867. The Improvement Trust, which demolished many of the slum districts and replaced them by new streets at a cost of over half a million sterling, was the outcome of this excellent work. To detail the work of Sir Henry Littlejohn in the field of public health would be to recount the entire sanitary history of Edinburgh for a period of 46 years—viz., until his resignation of the office in 1908. Special mention, however, must be made of four points in connexion with this work. To him is due, first, the origination and completion of the Hospital for the Treatment of Epidemic Diseases; secondly, the development of notification of infectious diseases; thirdly, the establishment of a higher standard of physical comfort among the working classes; and lastly, and in consequence, a progressive fall in the death-rate of the city from an average around 34 per 1000 in the "sixties" to 14·3 per 1000, its present figure in the last annual report. Sir Henry Littlejohn's work in this capacity brought him into intimate relations with the Board of Supervisors, now the Local Government Board for Scotland, by which his assistance was constantly sought in dealing with outbreaks of infectious disease and for reporting on insanitary conditions throughout the country. These reports were largely published, and constitute a valuable record of the progress of sanitation in Scotland. He was appointed medical officer to the Board in 1873, under the Public Health Act, and when his connexion therewith was severed in 1908 the Board paid a high tribute to his "half a century's strenuous work" in public health.

Another public appointment, the duties of which Sir Henry Littlejohn discharged with his customary acumen and thoroughness, was that of surgeon to the Edinburgh police, which, with his eminence as a teacher of forensic medicine, quite naturally led to his services being frequently utilised as medical adviser to the Crown in criminal cases. He was engaged in all the chief criminal trials of the last 50 years in Scotland, notably those of Pritchard and the Ardlamont case, and in this connexion he got together an important collection of relics of criminal trials which he presented to the University on his appointment as professor of forensic medicine. He was called on to conduct the analysis in all poisoning cases, and in civil cases also he was a highly esteemed expert witness. He was also repeatedly called as an expert in public health questions before committees of the House of Lords and House of Commons.

His extraneous activities were no less vigorous than his professional ones, for he associated himself with a large number of charitable organisations, and especially with most of those in the city of Edinburgh. He was chairman of the Society for the Prevention of Cruelty to Children. He was one of the founders of the Royal Hospital for Sick Children, and remained in close connexion therewith as a director to the end of his life. He also served for nine years on the board of the Royal Infirmary. As a lecturer Sir Henry Littlejohn was at once facile and practical. His lectures were for the most part extempore, and he rarely took anything into the lecture-room except a few jottings or cuttings from a newspaper sufficient to form a text for his discourse. The experience he had gained in his capacity as police surgeon and in the witness box, and his frequent consultation by the Crown in important criminal cases, enabled him to present the usually rather dry subject of forensic medicine in a practical light, while his manner was light and breezy, never tedious.

In 1875 Sir Henry Littlejohn was President of the Royal College of Surgeons of Edinburgh, and from 1883–85 President of the Edinburgh Medico-Chirurgical Society. When the Royal Institute of Public Health held its annual meeting in Edinburgh in 1893 he was chosen president, and his University conferred upon him its honorary degree of LL.D. He was knighted in 1895. In 1907, on the occasion of his retirement from the professorship of forensic medicine at the University, he was publicly presented with his portrait from the brush of Sir George Reid, ex-President of the Royal Scottish Academy.

He married Isabella Jane, daughter of Mr. H. Harvey, of London, by whom he leaves several daughters and one son, Professor Harvey Littlejohn, who succeeded his father in the chair of forensic medicine at Edinburgh University. The body was cremated in Glasgow on Oct. 2nd, the remains being deposited in the Dean Cemetery, Edinburgh, for Sir Henry Littlejohn was a strong supporter of cremation and Vice-President of the Scottish Cremation Society.

EDWARD HOOPER MAY, M.D. ST. AND., F.R.C.S. ENG.,

CONSULTING SURGEON, PRINCE OF WALES'S GENERAL HOSPITAL, N.

BY the death of Dr. E. Hooper May on Sept. 23rd the medical profession of the north of London has lost one of its oldest and most prominent members. A man of singularly retiring disposition, he possessed that peculiar charm given by genuine courtesy that characterised what is called the "old school" of medicine. Essentially a surgeon at heart, he yet made an ideal general practitioner, and throughout his long life he was ever foremost in efforts to advance the welfare of his neighbourhood. Perhaps he will be best remembered for his work in connexion with the Prince of Wales's General Hospital, of which he was one of the founders in 1867, and on the surgical staff of which he served until advancing years caused his retirement from the acting staff. Nothing gave him greater gratification than the rapid advance of this hospital, and there is no doubt that it is to his energy and devotion that the present position of the hospital among the London hospitals is due.

Born in 1831 in the house at Tottenham in which he died, he was educated at a private school and at St. Bartholomew's Hospital, where he was dresser to Edward Stanley and clinical clerk to Sir George Burrows. After qualifying in 1854 he went for an extra year's study to Edinburgh to be under Syme. For Syme he had the greatest admiration, and only a few days before his death he told a friend that he still thought Syme was the greatest surgeon of modern times. He also worked with Lister in 1855 at Edinburgh Infirmary. He obtained the F.R.C.S. Eng. by examination in 1856, and settled in practice at Tottenham, where his father, who came of old Quaker stock, had been in practice before him. In 1860 he took the degree of M.D. St. Andrews. In 1864 he assisted in establishing a dispensary, now known as the Tottenham and Edmonton General Dispensary, and in 1867 he was one of the founders of a hospital in connexion with a community of Evangelical Protestant deaconesses. This became the Tottenham Hospital, and eventually the Prince of Wales's General Hospital. Excellently trained for the work, he introduced Listerian principles at Tottenham, and he used to say that the carbolic spray was used earlier at Tottenham than at any other hospital, and given up earlier too. At this time he maintained a close friendship with, among others, Paget and Jonathan Hutchinson, sen., and Hughlings Jackson was one of his most intimate friends. Dr. May did the first nephro-lithotomy in England, though it was not done as a planned operation.

Dr. May did not make many contributions to medical literature. His opinion was widely sought, not only in surgical cases, and he did much consulting work in the north of London. To the end he retained perfectly his eyesight and hearing, and his interest in affairs and his mental activity were unabated. He leaves a widow and family, but none of his sons is in the profession.

JOHN FLETCHER LITTLE, M.B. CANTAB., M.R.C.P. LOND., J.P.,

LATE PHYSICIAN TO THE LONDON TEMPERANCE HOSPITAL AND MOUNT VERNON HOSPITAL FOR CONSUMPTION, ETC.

Dr. Fletcher Little, who died recently, was born in County Tipperary in 1843. His early education, including the first part of his medical training, was obtained in Dublin. In 1866 he took the qualifications of L.R.C.S., L.R.C.P. Edin. Shortly afterwards he commenced practice at Woolton, near Liverpool, an experience which he frequently afterwards used to quote as having been of much value to him. After some years he established himself at Ben Rhydding. It was at this time that he became interested in physical methods of treatment, especially in massage, and was able to pay a visit to the United States of America to study the ideas which found development later in treatment of the "Weir Mitchell" type. He left Yorkshire in 1879 and began medical study at Cambridge and Charing Cross Hospital, obtaining the degree of M.B. in 1888, and the Membership of the Royal College of Physicians of London in 1889. He had already opened a school for the training of both men and women in massage, one of the earliest institutions for this purpose in London.

Dr. Little acquired a considerable practice, but his wide interests soon induced him to give a large amount of time to public duties. He served for a considerable period on the London County Council and on the Marylebone borough council. In both places he gave evidence of a wide and sympathetic outlook on public affairs, and his advice was of much assistance on many occasions when matters involving the public health and medical interests were concerned. In politics he was an enthusiastic Liberal, and contested Oxford City in the Liberal interest in the year 1895. He held various medical posts of importance in London; for some time his medical work centred in the London Temperance Hospital and at the Mount Vernon Hospital, in both of which institutions he held the appointment of physician. A post to which he gave a large amount of care and attention was the medical officership of health of Harrow. He held this position up to the time of his death, never losing interest in Harrow and its neighbourhood, and had the strength to prepare the annual report of his work to the Harrow council for the year 1913.

To medical men in London Dr. Little was well known on account of his early advocacy and unfailing interest in schemes for post-graduate instruction. He had personally appreciated the value of this in his own career, and felt sure of the desirability of making post-graduate study easily obtainable. He assisted in starting a post-graduate course at Charing Cross Hospital, which was for many years very successful, and was almost the only course of instruction at the time arranged for post-graduates in London. Later, in association with the late Sir Jonathan Hutchinson, he was instrumental in starting the London post-graduate scheme which ultimately developed into the Medical Graduates' College and Polyclinic, an institution which has done so much good work for the medical profession. He was a man gifted with a sanguine temperament, enthusiastic in all that he undertook; difficulties were never too great to be overcome. His cheerfulness never stood him in better stead than during the long and trying illness which preceded his death.

Dr. Little was a member of a family consisting of three sisters and five brothers; two of his brothers, William and Joseph, entered the medical profession and practised in Australia.

SIR ALFRED EDWARD THOMSON, M.D. R.U.I.

THE death has occurred of Sir Alfred Thomson, of Cape Town, in a nursing home in Belfast, on Sept. 27th. Some four years ago he was the subject of gastro-enterostomy and, symptoms recurring, a second operation became necessary. This was successfully performed, but the patient's general strength failed and he succumbed in a few days. Sir Alfred Thomson, who was a son of a medical man at Bangor, county Down, studied at Queen's College, Belfast, and in 1886 graduated M.D. of the Royal University of Ireland. In 1891 he became a Member of the Royal College of Surgeons of England. He subsequently went to South Africa and settled down in Cape Town, where he built up an excellent practice and became visiting surgeon to the New Somerset Hospital. He was about 50 years of age at the time of his death and unmarried. Sir Alfred Thomson received his knighthood this year.

GEORGE GRESWELL, M.A. OXON. & CAPE OF GOOD HOPE, L.R.C.P. & S. EDIN., L.F.P. & S. GLASG.

WE regret to announce the death of Dr. George Greswell, a well-known practitioner of Louth, which took place at his residence on Sept. 16th following a severe chill.

Dr. Greswell, one of a family of nine brothers and sisters, received his preliminary education at King Edward VI. Grammar School, Louth, and afterwards went to Oxford University, where he had a distinguished career, obtaining an open exhibition at Christ Church, and afterwards graduating B.A. with honours in 1880. His medical studies were pursued at Edinburgh University, at St. Thomas's Hospital, and at Westminster Hospital. At the last institution he won an open scholarship, and having qualified by taking the L.R.C.P. & S. Edin., L.F.P. & S. Glasg., in 1892, he held various appointments in the Medical School, including that of demonstrator of practical histology. Later he was appointed lecturer in physical science under the Government of the Cape of Good Hope, having previously acted for two years as lecturer at the Diocesan College of Rondebosch, near Cape Town. On returning to England he took up medical practice at Grimsby for a time, and for the past 12 years had been in practice at his native town of Louth, in partnership with his brother.

Dr. Greswell was a frequent contributor to medical journals, and wrote several books, among them being "An Examination of the Theory of Evolution" and a "Veterinary Pharmacopœia and Manual of Comparative Therapy." He was also the author of "Health, Morals, and Longevity," and in conjunction with his brother of "The Vital Balance" and the "Wonderland of Evolution." Dr. Greswell will be greatly missed by his many friends and by the inhabitants of Louth, where he was highly esteemed for his learning, skill, and kindly nature.

EXETER ISOLATION HOSPITAL.—On Sept. 30th the foundation-stone of the new administrative block for the Exeter Isolation Hospital was laid by the mayor in the presence of a large gathering. The estimated cost of the building is £2700.

EPIDEMIC DISEASE IN WAR TIME.

To the Editor of THE LANCET.

SIR,—Now that not only so many of the larger hospitals in England, but also many private mansions, hotels, &c., are being converted into hospitals for the wounded, it is important that in all abundant means of isolation of patients with epidemic diseases should be provided in connexion before the outbreak of these diseases. The two main diseases to be anticipated are typhoid and epidemic dysentery. Isolated cases of these diseases can be treated in general wards of well-managed hospitals; but when aggregated, and particularly so when the mass of other patients have been exposed to cold, wet, irregular and often insufficient food, and have further had serious injuries, these diseases soon become epidemic.

Early isolation of all cases of these diseases, and also of carriers of these diseases, is the only method that is effective in checking the spread, and if reliance is placed on good nursing, food, and sanitation, without abundant means of isolation, these diseases will spread. I say nothing about cholera, because I understand that of this risk all are aware. It may be introduced, but epidemic dysentery is almost certain.

That the enormous amount of disease usual in war can be prevented is well exemplified in Dr. F. M. Sandwith's lectures on dysentery in THE LANCET of Sept. 5th, 1914, *et seq.* He points out that in the Japanese war against China in 1894 there were 3 deaths from disease to 1 from wounds, but rigid care and attention to sanitation bore their fruit in the Russo-Japanese war of 1904, as the figures were reversed—only 1 died from disease in proportion to 4 who died from wounds.

I am, Sir, yours faithfully,

Harley-street, W., Sept. 30th, 1914. C. W. DANIELS.

THE USE OF ALCOHOL ON THE BATTLEFIELD.

To the Editor of THE LANCET.

SIR,—The great wave of temperance which has swept over civilised peoples in recent years has gained much of its impetus from the efforts of many distinguished members of our own profession. It is therefore with great diffidence that I venture to raise the above question in your columns. Nor do I wish for a moment to advocate any essential modification in the non-alcoholic diet of our army in the field, however anxious I may be to prove my own thesis that the value of alcohol in the present campaign should not be under-estimated.

I will endeavour to put my points as concisely as possible. One of the arguments against the use of alcohol even medicinally, often quoted by scientific temperance lecturers, is the statement that alcohol inhibits phagocytosis, thereby impairing the first line of defence against the infections. I have never discovered the experimental evidence upon which this statement is made, and about five years ago I did some research work on my own account to ascertain its accuracy or otherwise. THE LANCET of Nov. 5th, 1910, published a research which I had made upon the influence of quinine and morphia on phagocytosis, and it was on the same lines that I endeavoured to investigate the influence of alcohol on the same process. My researches, though they entailed much intricate and laborious microscopic work, did not appear to me of sufficient importance to publish until I had confirmed my early conclusions by many repetitions of the experiments, nor was I anxious to enter the lists against the champions of total abstinence until I had made my weapons more effective. The experiments, so far as they went, showed clearly that large doses of alcohol (e.g., the equivalent of 10 oz. for an adult of 10 st.) destroyed the phagocytic action of the blood upon all the common pathogenic bacteria used in my experiments (pneumococci, B. coli, streptococci, and B. influenzæ), but that moderate doses (2 oz.) distinctly increased phagocytic action against these organisms. This confirmed conclusions which I had come to in clinical observations spread over 20 years of active practice, and I have met many able practitioners who have agreed with me on this point.

Last year, at the International Congress of Medicine, a paper was contributed to the section of Bacteriology and Immunity by Professor Besredka, of the Pasteur Institute, on the subject of anaphylaxis.[1] One series of his experiments quoted therein showed how anaphylaxis could be brought about in test animals. They received an injection of some foreign proteid, and on a subsequent date had become so sensitive to this that a second injection produced rapidly fatal results. Another series of experiments was made in which the test animals were divided into two sets; all received the same initial dose of proteid, and all received the same lethal dose on the day of greatest sensitiveness, but one half—the controlled animals—during the interval had been given a certain amount of alcohol. All the teetotal animals died and all the alcoholics survived. It was evident that the alcohol had in some fashion neutralised the poison, stimulated the animal's blood to develop an antitoxin, or narcotised the nervous system so that the higher centres were impervious for a time, and the virulence of the poison abated before the protective effect of the alcohol had passed away.

It is conceivable that, given an injury—say an infected wound—followed by a prolonged exposure to cold and damp, and also in many diseases, conditions are met with closely analogous to this experimental anaphylaxis. Many apparently healthy people are unwitting carriers of pathogenic bacteria, such as various types of influenza bacilli, pneumococci, the large family of streptococci, and the B. coli group. These only need some depressing factor in the shape of danger, hunger, damp, and cold to lose their normal resistance to the germs and fall an easy prey to acute infections which may assume the form of influenzal fever, rheumatism, pneumonia, bronchitis, or septicæmia. When numbers are herded together severe epidemics may easily arise from such a focus, and a virus which has suddenly taken on a greater degree of virulence spreads very rapidly. I have not the slightest doubt that in the first stages of most of this group of cases moderate doses of alcohol are valuable in aiding the natural resistance of blood and tissues. It is too late to be of any service when the patient's tissues are already infiltrated with excess of toxin, and I believe that it is the futile attempts to save dying men by the administration of alcohol which have led so many able observers to say that alcohol is useless as a medicine.

---

[1] A translation of the paper was published in THE LANCET of August 16th, 1913, p. 462

I suggest that if there were under the control of company officers a supply of alcohol which could be served out at their discretion, very much in the same way that our naval officers ordered tots of Jamaica rum to the spent sailors in the days of Nelson, there would not be much fear of abuse. It would be distinctly understood that it was an emergency ration, and since the dose need not exceed 1½ oz. of alcohol (good London gin, Scotch whisky, Jamaica rum, or good cognac if available) it would not form a very bulky addition to the ammunition columns. Our heroic troops are not likely to be brutalised by this "prophylactic" use of alcohol, and if it prevented the death of only 1 in every 100 of them it would be well worth the cost and trouble of supply. If I have not misread Mercier's delectable writings upon alcohol and insanity, it is not the use of alcohol which drives men mad, but the insane man who makes insane use of it. I am, Sir, yours faithfully,

H. LYON SMITH.

Bentinck-street, W., Oct. 1st, 1914.

THE BRITISH PHARMACOPŒIA, 1914.

To the Editor of THE LANCET.

SIR,—The new issue of the British Pharmacopœia (1914) will, as has been already announced in your columns, be published on Dec. 31st, 1914. Inquiries have reached me from more than one source with regard to the extent to which the Medical Council will permit the use of the contents of the British Pharmacopœia in medical, pharmaceutical, and kindred works which are about to appear or may hereafter be published. I am accordingly instructed, on behalf of the Council, to say that the Council wholly reserve their copyright in the new work; and that substantial extracts from it must on no account be published without the Council's express sanction. At the same time, no objection will be taken to such reasonable reference to the facts and figures therein set forth as may be properly made for purposes of criticism, review, and summary, or of study and research, but no information of any kind derived from the new issue may be published in book form before Dec. 31st, 1914.

Advance copies[1] of the British Pharmacopœia, 1914, are now accessible at this office, and at 54, George-square, Edinburgh, and 35, Dawson-street, Dublin, for the inspection of the public, from 10 A.M. to 4 P.M. daily (Saturdays 1 P.M.) in order to give to manufacturers, pharmacists, and others interested, an opportunity of ascertaining the changes that are about to be made in official requirements, and of making the necessary arrangements to meet them.

Every person who takes advantage of this opportunity will be expected to observe the conditions above indicated, and will be required to sign an undertaking to that effect.

I shall be obliged if you will insert this letter in your next issue.

I am, Sir, yours faithfully,

A. J. COCKINGTON,
Acting Registrar.

General Council of Medical Education and Registration of
the United Kingdom, Oxford-street, London, W.,
Sept. 30th, 1914.

PS.—The Medical Council Act, 1862, provides that—

"The exclusive right of publishing, printing, and selling the said Pharmacopœia shall vest in the said General Council"

The Copyright Act, 1911, may also be quoted in this connexion:—

"2. (1) Copyright in a work shall be deemed to be infringed by any person who, without the consent of the owner of the copyright, does anything the sole right to do which is by this Act conferred on the owner of the copyright; provided that the following acts shall not constitute an infringement of copyright: (1) Any fair dealing with any work for the purposes of private study, research, criticism, review, or newspaper summary."

IMPERFECTIONS IN THE CUMBERLAND INFIRMARY.

To the Editor of THE LANCET.

SIR,—In the *Hospital* for Sept. 19th may be found a contribution by Sir Henry Burdett, K.C.B., K.C.V.O., on which a few comments are needed. The governors, the committee, and the staff of the Cumberland Infirmary, both honorary and resident, will all feel grateful to the writer of the article for his criticisms and suggestions, even if certain inaccuracies mar his statements.

Sir Henry Burdett contrasts the condition of the infirmary in 1893 with his impressions gathered in June, 1914, and it would seem that so far from improving, the hospital has deteriorated during this period. It is true that he draws attention to certain structural improvements and additions which have cost some £30,000, but he describes a completely equipped ophthalmic department as a "new ophthalmoscope room"! I may mention one of the advances made in the Cumberland Infirmary since 1893 which Sir Henry Burdett has seemingly overlooked. In 1899 a new aseptic operating room, one of the first in the provinces, was completed, but the report credits us with the possession of a new clinical room to each ward which up to the present we have not acquired.

Sir Henry Burdett causes a smile to spread when he writes: "We gathered the impression that at present there is little or no spirit or life in the place. ...... There was a lack of smart contented briskness in the general atmosphere and work going on in the wards." Well, there is life and spirit enough left to repudiate so hasty a judgment, which to those who have other than a superficial knowledge of the infirmary must seem both featureless and uninformed. Sir Henry Burdett is of opinion that the "Cumberland Infirmary is one of those institutions which require someone in authority with technical knowledge and experience who is constantly devoting attention and time to the supervision and enforcement of smartness throughout the wards and those portions of the establishment which are included in the hospital section." One wonders from what source Sir Henry Burdett gathered that there is a pressing necessity for a sort of supervising inspector who would create the smartness which is lacking in our hospital. All of us have some Utopian plans and ideas, but it is usual to cut the coat according to the cloth in hand, and I question if a superintendent (such as may be found in larger hospitals) would help us very much, even if his services were gratuitous. Sir Henry Burdett thinks otherwise, but in spite of the opinion his wide experiences have helped him to form, I think we know how to adapt our expenditure to our means, rather more certainly than he at his visit appears to have been able to do.

"The administration has been sadly changed for the worst." I pick out this condemnatory opinion with considerable amazement, to use a mild expression, and assume that the committee, being the body responsible, has to bear the brunt of this unjustifiable attack, and I am more than at a loss to see where Sir Henry Burdett can have gathered materials for so sweeping a dictum.

---

[1] A few typographical errors detected in these advance copies will be corrected in the official issue. The editors will be obliged for the intimation of any errata which may have escaped their notice.

I quite agree with Sir Henry Burdett "that the real happiness and efficiency of a hospital must depend largely upon the presence or absence of devotion and zeal, coupled with a keen interest in the work among all sections of the staff." Sir Henry Burdett, with marvellous insight during short visit, found the staff of the Cumberland Infirmary lacking in these attributes. Sir Henry Burdett in his mercy refrains from stating the conclusions which his inquiries led him to arrive at, but this restraint is cast off in his summing up of the committee of management, which he thinks has greatly deteriorated. It is well known that the composition of a committee depends on mixed circumstances, and our committee, in accordance with modern requirements, consists of a fair representation of all sections of the community. Sir Henry Burdett would imply that wider representation begets narrower views, for he asks, "Has there been a gradual elimination of the former principles which led some of the most distinguished residents within the county to take an active part in the management?"

Sir Henry Burdett opines that only an investigation, conducted by an expert, could cope with what he considers to be the mismanagement of the infirmary by incapable officials who have, in his opinion, usurped the position of control they are not properly qualified to exert. It seems that this view must be the result of some misapprehension on Sir Henry Burdett's part, for I am almost certain that the committee would repudiate the statement that there has been any interference with their scheme of management. His suggestion of a landscape gardener is quite a good one, but we cannot run the risk of the criticism of our subscribers, and in point of fact there is not a hospital in the country with so fine a site and so splendid a distant view. We cannot afford a gardener of any kind, and there are not many people living in Cumberland who keep a landscape gardener or even consult one; nevertheless, it is a provision to be kept in mind when our affairs are sufficiently prosperous and our supporters are urging us on to take such a step.

With regard to Sir Henry Burdett's suggestion that we should leave the whole of the nursing and domestic affairs directly under the control of a lady superintendent, who should have the assistance of a housekeeper, one wonders what he found so far wrong with the matron Miss Sylvia Parker, who gave him the pleasure of taking him round the hospital. In a larger hospital the sisters, nurses, and probationers can be quite well placed altogether under a superintendent of nurses and a housekeeper employed to look after the commissariat, but in a small provincial hospital like the Cumberland Infirmary care has to be taken not to swallow up the income with a larger staff than is actually needful. Sir Henry Burdett would allow us a resident medical officer (I presume a secretary also), a lady superintendent, and a housekeeper, and these together with our two house surgeons would make a big hole in £1000 a year—a luxury we are quite unable to afford even if it was really essential, which, I think, is very doubtful.

I cannot help thinking that Sir Henry Burdett's conclusions are based either on inaccurate deductions or that he has been supplied with data that are for the most part fancies. Open as we are to suggestions and grateful for any just criticism, I can hardly, in justice to the Cumberland Infirmary, allow some of Sir Henry Burdett's statements to pass without these few comments which I have sent to THE LANCET as well as to the *Hospital*.

I am, Sir, yours faithfully,

Carlisle, Oct. 4th, 1914. H. A. LEDIARD.

OSTEO-ARTHRITIS.

To the Editor of THE LANCET.

SIR,—The correspondence in THE LANCET concerning osteo-arthritis has interested me very much. I have long held that wherever there is neuritis there is always arthritis. The latter may not be severe and may not pass to the erosion stage. I agree with Dr. F. J. Poynton that any known micro-organism may set up any known form of arthritis. Where we have only pulpy swelling the affection may be entirely due to toxins. In osteo-arthritis the actual germs are present in the joint. I am sure we are all very much indebted to Dr. R. L. J. Llewellyn and Dr. A. Bassett Jones for the hints on diagnosis. Their suggestions, however, as to treatment are meagre. Given that osteo-arthritis is due to germs, then surely something that definitely combats germs is useful. I did not notice any mention of changes in the spinal cord in these cases. Orr and Rows have shown how germs may reach the cord along nerve sheaths. P. W. Latham has shown the value of spinal blistering in cases of arthritis, and I am strongly of opinion that it is of great value in early and even late cases of osteo-arthritis in remedying to some extent the changes in the cord and checking the ravages of germs. Local applications of heat may do actual harm in some cases by attracting toxins to damaged areas.

I am, Sir, yours faithfully,

Bournemouth, Oct. 1st, 1914. W. J. MIDELTON.

THE LONDON PANEL COMMITTEE AND A "THANKOFFERING."

To the Editor of THE LANCET.

SIR,—In your report of the proceedings of the London Panel Committee on Sept. 29th it is stated that the proposal to present an ambulance to the Red Cross Society as a thankoffering for the receipt of £90,000 was carried. Though the chairman made a humorous reference to the fact that the Commissioners had at last decided to disburse this money, there was nothing in the resolution to suggest that the gift was to be a thankoffering. As I was sent to the Panel Committee to represent those practitioners of St. Marylebone who are robbed through the ineptitude of trying to run a commercial undertaking on "culture," I could only ironically have voted for the gift as a thankoffering.

I should not have called attention to this matter were it not for the fact that extracts from THE LANCET appear in the lay papers, and from the wording of the report it might be inferred that the members of the Panel Committee were overwhelmed with gratitude at receiving something to which they were not entitled. Though some members may have regarded the proposal "to contribute not more than a guinea" as a sop to conscience on receiving remuneration really due to their neighbours, this was not expressed in the resolution.

I am, Sir, yours faithfully,

Wells-street, W., Oct. 5th, 1914. J. M. TWENTYMAN.

THE TREATMENT OF STREPTOCOCCAL INFECTIONS.

To the Editor of THE LANCET.

SIR,—In a leading article in THE LANCET of Oct. 3rd, in which some reference under this heading is made to a paper of mine appearing in the same issue, it is suggested that the hæmolysin of the streptococcus is possibly identical with its endotoxin. Although this may be the case, it is to the possible identity of streptococcal hæmolysin with a genuine exotoxin that I wished to draw attention in my paper. As I have perhaps not made this sufficiently clear, and as the existence of a genuine exotoxin in streptococcal cultures has been frequently denied, it may be stated that in Braun's experiments rabbits were killed within 24 hours by the intravenous injection of 5 c.c. of filtrates of the cultures of certain streptococci. In the experiments carried out by Dr. McNee and myself similar results were obtained with larger doses of filtrate. Apart from the usual test of the sterility of the filtrate our results were farther controlled in the following way:—The filtrate from a culture was divided into two portions, and while one of these was injected directly to a rabbit, the other was incubated over night, a proceeding which almost completely destroyed its hæmolytic power, and injected to a second rabbit. Whereas the first rabbit usually showed signs of severe intoxication and often died, the second was never inconvenienced. This result appeared to us to justify the conclusion that certain streptococci produced a genuine although very labile exotoxin, which was closely allied to streptococcal hæmolysin.

I am, Sir, yours faithfully,

JAMES WALTER MCLEOD,
Assistant Lecturer in Pathology, Medical School,
Charing Cross Hospital.

HELICON.

To the Editor of THE LANCET.

SIR,—One is bound to endorse the Government policy "not to close all German concerns when they were carried on for the benefit of British labour." What I suggest—the prescribing of British helicon instead of German aspirin—would not have that tendency.

The same amount would be expended for British labour, but the profits would go into the right pockets, not into those of our enemy.

I am, Sir, yours faithfully,

Hove, Oct. 5th, 1914. EDWARD TREVES.

TREATMENT OF THE WOUNDED IN THIS COUNTRY.

To the Editor of THE LANCET.

SIR,—Even medical men may not have too clear an idea of the scheme upon which the wounded in the war are being dealt with in this country, while it is obvious from communications that have appeared in the daily press that many of the public have no conception of the procedure. The articles on the organisation of medical service in the field will do good, but have you sufficiently shown that in the processes of collecting, sifting, and shifting a large proportion of the most serious cases will be retained abroad? There is little information yet as to the work done by the Royal Army Medical Corps with the Expeditionary Force, but that its resources have been sorely tried is well known and that its personnel has exhibited great courage and devotion can be gleaned. It is right to insist that the character and course of the campaign have made the prompt care of the wounded impossible sometimes.

I am, Sir, yours faithfully,

Oct. 5th, 1914. R. W.

THE NATIONAL INSURANCE ACT.

THE WAR AND THE REVISION OF THE MEDICAL BENEFIT REGULATIONS.

IT was generally regarded as likely that considerable revision of the medical benefit regulations and of the terms and conditions of medical service under the Insurance Acts would take place at the end of the current year. The Commissioners have confirmed this in the memorandum to Insurance Committees issued last week, stating that the preparation of revised regulations to come into force on Jan 1st., 1915, had for some time engaged their attention when war intervened, bringing with it the abnormal conditions with which the country is now becoming familiar. In these circumstances the Commissioners, although convinced of the desirability of the changes which they intended to make, have decided that any thorough revision of the existing regulations at the present juncture would involve disadvantages outweighing any benefit which might be expected to accrue therefrom. With this decision the medical profession will heartily agree, and will recognise the spirit of consideration shown for its members in the unprecedented and unforeseen situations in which many of them now find themselves. The Commissioners sum up the position by pointing out that members of Insurance Committees and of the medical and pharmaceutical professions are preoccupied with special problems, local or national, and are voluntarily undertaking exceptional duties in the public interest or in the service of their country which makes it desirable to avoid as far as possible the imposing upon them of the consultations and negotiations involved by substantial revision of the regulations. Further, the Commissioners take into account the number of panel practitioners abroad on active service (with whom they might have included those absent from their practices, although not yet on active service abroad) and express themselves disinclined to introduce changes with regard to which no notice of their intentions could be given "to a section of the medical profession so specially entitled to consideration." As, however, it is possible that the end of war might enable regulations to be considered before the last months of 1915, the Commissioners have decided to make a change as regards the date on which alterations of agreements, both with medical men and druggists, may take place. A draft regulation is accordingly issued by which, as regards the year 1915, the Joint Committee shall have power to alter terms of service upon giving notice to medical practitioners not less than eight weeks before the date of the alteration proposed and not less than six weeks in the case of druggists. The articles in the regulations applying to changes in the terms of agreements are to apply as though the date which may thus be fixed at any time during 1915 were the commencement of a year as contemplated by those articles. Any change of regulations would, however, probably be made at the beginning of a quarter, and is not likely to take place before June 30th, 1915. The only other alteration of existing conditions now in view consists in the proposed substitution of a uniform scheme of certification, to be imposed by the Commissioners, for the existing system of certification in accordance with the rules of a particular society or committee. This would carry into effect, the Commissioners believe, the wishes of the medical profession upon a point as to which it has been widely consulted.

PREGNANCY AND SICKNESS OR DISABLEMENT BENEFIT.

The Insurance Commissioners having recently informed Approved Societies that no distinction should be drawn between incapacity due to pregnancy and that arising from other causes, so far as the payment of benefits is concerned, have issued a memorandum to the same effect to medical practitioners. It states that if a practitioner on the panel is satisfied as to the incapacity for work of his patient a certificate should not be withheld on the ground that the incapacity is due to, or accompanied by, pregnancy. As, however, a special grant has been provided for the cases referred to, incapacity directly or indirectly due to pregnancy should be clearly indicated on the certificate. Practitioners are also warned that the provision of benefit for the pregnant does not affect the criterion of incapacity; that is to say, certificates must not merely be given on account of pregnancy, but only where the medical man is satisfied that the insured person is rendered incapable of work. The action of the Commissioners in this matter may be regarded as part of a Government policy of organised attention to the care of infant life—a subject with which we dealt recently in a leading article on the Government grants for maternity and child welfare.[1]

INSURANCE AND WAR SERVICE.

The Commissioners call attention to the benefits provided for seamen, marines, and soldiers under the Insurance Acts. The authorities will pay 3*d.* weekly for such, deducting 1½*d.* from their pay; but men of the Naval Reserves, Territorial Force, and New Army not insured before mobilisation or enlistment may choose whether contributions shall be paid in respect of them, or whether they will forfeit the benefits to which they would become entitled by insurance. Civilian contributions and arrears do not have to be paid during service, and maternity benefit is the only benefit which survives while service continues. The Commissioners in a circular (Leaflet 29) describe the steps which a wife must take to secure maternity benefit while her husband is serving. Particulars are also given of the benefits to be secured on discharge by insurance during service, through Approved Societies and out of the Navy and Army Insurance Fund.

SANATORIUMS UNDER THE ACT.

The list of sanatoriums approved by the Local Government Board under the National Insurance Act, 1911, for England and Wales has now been revised up to Oct. 1st, 1914, and a copy of the revised list of the approved sanatoriums for the treatment of persons suffering from tuberculosis and resident in England (excluding Monmouthshire) may be obtained, either directly or through any bookseller, from Messrs. Wyman and Sons, Limited, 29, Breams-buildings, Fetter-lane, E.C. Sanatoriums for the treatment of insured persons suffering from tuberculosis and resident in Wales (including Monmouthshire) are now subject to the approval of the Welsh Insurance Commissioners.

THE WAR.

SIR ALFRED KEOGH.

Sir Alfred Keogh, who has been acting as Chief Commissioner with the British Red Cross Society in Paris, has returned to England and taken up a medical appointment at the War Office.

THE WOUNDS OF THE PRESENT CAMPAIGN.

We publish elsewhere some notes upon the wounds of the present campaign by Mr. G. H. Makins, C.B., Consulting Surgeon to the Forces.

GERMANY IN WAR TIME.

An English medical correspondent in Switzerland, with free and early access to medical and other periodicals from Germany, sends us the following notes which we think will prove of interest to medical readers in this country. It will be seen that the notes range over a large number of subjects only connected by the common bonds of war conditions.

Food-supply of the civil population.—A memorandum, drawn up by well-known medical men, recommends the careful saving of wheat flour, since only two-thirds of this is home grown, and the addition of rye flour which normally is exported from Germany. The bran, amounting to 20–30 per cent. of wheat flour, should not be used as fodder but mixed with the flour; and small loaves can be made of bran and rye alone. The use of meat must be restricted, remembering that Germany, next to England, has the largest consumption per head (107 lb. per year). One portion of meat a day is enough, and this economy is especially the duty of the rich for the sake of example. Veal must be given up and some reduction made in the total number of oxen and bullocks, thereby liberating some grazing ground for growing corn. Cheese should become an essential article of diet, making with bran bread, milk, and potatoes an excellent and complete food. Vegetables are to be grown everywhere—in the cornfields between the crops and on dug-up lawns in towns. Maize, chestnuts, peas, lentils, beans, and rice are to take their share in saving corn. The production of beer must be restricted, and people should learn to quench their thirst with water, a sacrifice small in comparison with that of the soldiers in the field. The barley meal so saved can be added in the proportion of 10 per cent. to rye bread, with a little bean meal to avoid dryness. Potatoes should be used neither for feeding cattle nor for making schnaps, and potato meal is also useful for bread making. In this way 20 per cent. of the available rye could be saved in view of a possible bad harvest in 1915. The memorandum, while advising these precautions, disclaims any occasion for anxiety of famine.

Diseases in the fields of war.—Improved hygiene makes itself felt in the more recent wars. In the Crimea for each soldier killed on the field 1·7 died later from wounds, and 6·4 from disease. On the German side in 1870 1·6 died from wounds and only 0·9 from disease. Up to Sept. 10th the health of the German army was reported good, but there was stated to be pulmonary plague in Poland, small-pox in Russia, Belgium, and France, and cholera in Podolia and Warsaw. The German Kaiserin has issued a circular expressing the urgent wish that tuberculosis effort should not be suspended on account of the war. Up to August 17th 2000 Germans had availed themselves of the special qualifying medical examination.

Personalia.—The eldest son of the Bavarian Crown Prince has died within 36 hours of acute poliomyelitis, a disease specially endemic in Upper Bavaria, 44 cases being notified from Munich within less than a year. Some little rivalry has occurred amongst German scientists in getting rid of medals presented to them by English learned societies. Röntgen, of X ray fame, and the physicist Lanard, have given the gold value of their Royal Society medals to help the relatives of fallen soldiers; and Schmid, the pharmacologist of Marburg, followed suit with the Hanbury medal. The wave of patriotic feeling in Germany extends also to medical circles. There is a widespread movement to rid the language of all foreign medical words, and still longer and more unwieldy compounds are to be expected. The following instance of carrying this spirit somewhat further than in corresponding English circles may be of interest. An English medical man asked the publishers of one of the principal German medical papers for the translation rights into English of a vade-mecum for surgeons at the front. The publisher telegraphed in reply: "English edition unnecessary, since the cut-up (*verhauen*) English soldiers are at present in German hospitals and are being treated there according to the German edition"; and the jest was considered sufficiently good to reproduce in all the principal German dailies.

---

[1] THE LANCET, Sept. 26th, 1914, p. 805.

THE TERRITORIALS AND CLEANLINESS.

Although everyone can appreciate that all connected with the War Office have their hands full at the present moment, we still think it unfortunate that more attention has not been given to the very urgent problem of the cleansing of the undergarments of the Territorials and other newly raised troops which are at present in training in this country. This is not a matter which can be left to the individual initiative of men who are camped out in strange localities. A proper organisation should be instituted, and we suggest that in every camp a depôt tent should be established where the men could hand in their soiled underwear. Thence it could be sent in bulk to a laundry in the neighbourhood, where it could be cleansed and returned in bulk to the camp to be distributed to the owners. We understand that the Federation of Laundry Associations are perfectly willing to make the necessary arrangements with laundries favourably situated for doing the work, which would be undertaken at as near cost price as possible; the only thing necessary is proper organisation to be established by the officers in charge of the camps. We are informed that up to the present no detailed arrangements with regard to laundries have been made, and if this be so we think that the matter deserves immediate attention. The managers of laundries where odd parcels have been received from the recruits have already discovered vermin in the garments, and unless proper precautions are taken there is no doubt that a very annoying disease will spread rapidly. It is obvious that with men drawn from all ranks of life closely packed together in tents this difficulty is bound to arise unless suitable measures are found to deal with it. On campaigns, as every old soldier knows, the trouble is almost sure to occur, but it should not present itself in troops which have not yet gone to the front.

THE CARE OF THE WOUNDED IN PARIS.

A valued correspondent resident in Paris, who unwillingly left the city when a siege looked imminent, and when the authorities were pressing on all who would be unable to take a personal part in the defences the necessity for taking *les bouches inutiles* elsewhere, was able to return in a few days, and has sent us the following letter:—

Coming back to Paris after a short absence I was struck by the contrast between the stagnation in all the usual occupations of daily life and the immense activity among the many organisations for dealing with the sick and wounded. Every organisation created for this purpose is under the final authority of the French Military Service de Santé. Up to the time of writing it has controlled the collection of the wounded on the battlefields and their distribution to the different hospitals. The advantages of a central authority were, however, diminished by the increasing difficulty of rapidly transporting large numbers of wounded, and, perhaps not readily enough, it was decided to utilise the voluntary assistance so freely offered. It has until recently been very difficult to obtain permission for motors to enter the fighting zone, owing to the occasional misuse of such permits, but it is now recognised that delay in transport must be avoided at all costs, and the Red Cross societies are permitted to send their own motors to collect the wounded on the battlefields.

The distribution of the wounded among the hospitals has been entirely in the hands of the military authorities. They believed that in first filling the provincial hospitals they would avoid the danger of a possible epidemic in Paris, increase the chances of the patients' speedy recovery in country air, and have more empty beds to be used in case the enemy succeeded in fighting up to the gates of Paris. The theory was excellent, but a good deal of dissatisfaction has been caused by the trying and sometimes fatal delays due to the difficulties of train service, monopolised as this was largely forced to be by the transport of troops and supplies. The wounded have sometimes spent three or four days in the train without the attentions of trained nurses at a time when Paris was literally filled with empty hospitals. The Government has now issued an official note from Bordeaux, stating that the unfortunate necessity for hurriedly transporting wounded stretched on straw in wagons previously used for transporting horses was due to the German habit of disregarding the Geneva Convention and bombarding the hospitals and ambulances. The note points out that if these hurried evacuations have had serious results in some cases they have undoubtedly saved the lives of the majority.

Orders have now been issued permitting Red Cross nurses to be in attendance on the trains, and the ambulance motor service which will be run by each hospital will relieve the congestion in the railway transport, always a difficult problem where the movement and victualling of troops and the transport of ammunition must take precedence over the evacuation of the wounded.

While the French are still reserving the Paris hospitals for a possible emergency, the greatest activity is seen among those under English direction. Five hospitals have been organised by the Paris section of the British Red Cross Society and are in full working order, though the section has scarcely been in existence a month. The work begun in the home of the general secretary, Mr. C. Stanhope, has grown so rapidly that the president, Dr. Leonard Robinson, Mr. Bernard Harrison, and the entire staff have moved their headquarters to the Hôtel d'Iéna, which has been lent by the proprietress. A good service of ambulance motor-cars has been arranged for the transport of the wounded from the base of operations to the hospitals organised by this Paris branch. One of them is at the British Hertford Hospital at Levallois-Perret, another in the Hôtel Astoria is directed by the Baronne Le Lasseur, a third in the nursing home of Dr. Suzor, a fourth in the home of Vicomtesse Antoine de Contades and her brother, and a fifth in the Château de Laversine, offered by Baron Robert de Rothschild, is already filled under the direction of Dr. Kaye. The Rev. H. Briggs and a staff of ten chaplains are working hard among all the different institutions where the English wounded are found. Of course, the English soldiers are generally drafted to the English hospitals, but no special attempt seems to have been made to separate the different nationalities. 330 wounded Germans were being cared for at the Val-de-Grâce Military Hospital last week, and there were 50 English wounded in the auxiliary military hospitals in the Lycée Buffon, Boulevard Pasteur. The sympathy of the French for the English is remarkable. 500 people attended the funeral of an English private two days ago and there were many flowers brought for the coffin of the unknown ally. Another English hospital under the direction of the Union des Femmes de France was organised by Dr. Louisa Garrett Anderson and a complete staff of women surgeons, doctors, and nurses. The help of this unit was gratefully accepted by the French Government. The hospital is installed in the building lately completed for the Hotel Claridge in the Champs Elysées. In an incredibly short space of time the shavings and rubbish left by the builders were cleared away and all the paraphernalia of the spacious wards installed. There were from 60 to 70 cases there last week, and an average of 12 have been received every day, but here as elsewhere it is impossible to quote numbers which change constantly. Many very serious cases have been taken here, some of the men being brought in moribund. Most of the wounds are in the legs and arms, and nearly all are from shrapnel. One man had the heavy round iron cap of a shell in the abdominal cavity for seven days. The lighter cases are being sent out to the hospital organised in the Trianon Palace Hotel at Versailles. No cases of tetanus have been received here as yet, but several cases have been brought in to other hospitals. One of the largest and most complete of the new voluntary hospitals in Paris is the American ambulance at Neuilly. The huge new building of the Lycée Pasteur in the Boulevard d'Inkermann has been fitted up with every appliance that money can buy, and the patients are cared for by a staff of American doctors and nurses.

Twenty motor-cars go out daily to pick up the wounded, and their return in the late afternoon is eagerly waited for by a large crowd of people.

Since the authorities do not wish to have any more hospitals in Paris, the £25,000 offered to France by the Canadian Government to establish a Canadian ambulance will be used to organise a hospital outside Paris.

At a meeting in Paris between Sir Alfred Keogh and the other Red Cross Commissioners, Dr. Robinson, the chairman of the Paris branch of the British Red Cross Society, the members of the committee, Lord Robert Cecil and Mr. Stanley, it was decided that as the great need of the moment was ambulances, all those at present at Boulogne and Amiens should be at once brought to Paris. Mr. Stanley undertook to send out ambulances as quickly as they could be shipped across, and for that purpose it was decided to charter a special vessel.

THE BRITISH RED CROSS SOCIETY.

The following is a summary for the week ending Oct. 7th of the work done by the Society :—

Paris.—The various hospitals in Paris are now doing excellent work, and these have been augmented by an additional personnel during the past week, and also by the Scottish unit which is now with the Red Cross Hospital at the Hotel Astoria. The equipment of the 50-bed hospital of the Scottish unit for Paris was despatched on Oct. 1st and reached Rouen on Monday, Oct. 5th, for Paris. The personnel reached Paris on Oct. 3rd, and is located in the upper floor of the Red Cross Hospital at the Hotel Astoria. Active steps are being taken for the despatch of a Scottish unit of 10 motor ambulances, three closed cars, and three lorries covered, to work with the unit, and suitable personnel has been engaged. These motor ambulances have all new chassis, and will probably have a body approved by the British Red Cross Society. It is hoped that some of these will be despatched by Tuesday by steamer from Glasgow to Rouen. The motor ambulances are proving of great and invaluable service to the hospitals. The depôt of stores established by the Scottish branch at Rouen has been replenished from time to time with all the articles needed, as suggested by the society or by the advice of the Scottish Deputy Commissioner on the spot.

Personnel of the hospitals.—During the past week the society has despatched two units to Paris. The first consisted of 10 surgeons, 10 dressers, 44 orderlies, and 33 nurses, and the second of 15 surgeons and 50 nurses. Five surgeons and 4 orderlies have also been sent to Amiens. On Oct. 3rd 3 nurses went to Dieppe and 1 nurse (with the surgeon and X ray plant) to Paris. On the 6th, 50 nurses left for Paris and 3 nurses for Aix-les-Baines, and on the 7th 6 nurses left for Dieppe.

Stores and transport department.—During the week ending Oct. 7th 28 hospitals in Great Britain have been provided with medical stores and comforts. The shipments to France have been very extensive. At Rouen the yacht *Sunbeam* delivered 458 cases of stores, and in addition large consignments have been forwarded to St. Nazaire, St. Malo, Paris, and Dinard. The steamship *Aunis* has been chartered and will sail from London direct to Paris. She will carry about 500 tons of cargo and has been chartered at the rate of 400 francs per day, plus coal, pilotage, harbour dues, and stevedore's pay. The total should not exceed £1000 per month, which is reckoned by the Peninsular and Oriental Company to be a very moderate price. She will ply between London, Rouen, and Paris, taking stores. She can also be sent as far as Bordeaux round the continent if necessary. The stores and transport department is shipping to Paris 1000 cases of medical stores, clothing, and comforts, and further over 2000 blankets, also 80 beds with bedding complete. This represents approximately hospital kit, medical stores, and bedding for about 2000 men. Messengers will leave London for the Chief Commissioner on Tuesdays and Saturdays, returning Thursdays and Fridays unless the Chief Commissioner otherwise determines. The names of those willing to serve as messengers are as follows :—Lord Annaly, F. Hodgson, Esq., Hon. L. Holland, H. Hudson, Esq., Colonel Johnston, D.S.O., I. Malcolm, Esq., M.P., D. O. Malcolm, Esq., C. M. Marling, Esq., C.B., C.M.G., Hon. Sir S. McDonnell, G.C.V.O., Sir W. Miller, Bart., Lord Onslow, D. Pender, Esq., Conway Seymour, Esq., C. Westmacott, Esq., and H. Samuelson, Esq.

THE THREAT OF CHOLERA IN EUROPE.

A communication which we publish this week from Dr. F. G. Clemow, C.M.G., the British delegate on the International Board of Health at Constantinople, deals with the danger from cholera and plague, which existing endemically in their eastern bounds, may become prevalent in the West through military operations. The Board of Trade has received through the Foreign Office official notice that Catania and Piræus are infected with plague. But, as Dr. Clemow says, plague is a disease that offers far less menace to fighting forces than does cholera, and it is with his summary of recent cholera prevalence in the Near East that readers will mostly be concerned. It would seem that Russia by the beginning of September was fairly free from cholera, and that the rumours of its presence in Black Sea ports were not true. But there appears to be no doubt that cholera made its appearance among the wounded in Hungary at least a month ago, so that there must have been some cases in Galicia when war broke out. The Austrian Public Health Department has made a statement that the affected cases which appeared in Moravia and Silesia were all among soldiers sent back from the seat of war. Of the existence of the disease among these there is no doubt, but of its degree of prevalence no one can speak certainly, the presence of dysentery complicating the diagnosis. Dysentery has probably got out of hand, as there is a serious shortage of medical attention with the Austrian troops, although the German troops are accompanied by a large personnel of medical officers and their attendant men. Any absence of medical supervision is disastrous where dysentery is concerned, as early diagnosis and the free use of means of isolation are required to prevent the spread of a disease which is disastrous to armies in time of war.

FIRE PRECAUTIONS IN EMERGENCY HOSPITALS.

The British Fire Prevention Committee desire it to be known to the management of the hospitals and convalescent homes, permanent and temporary, doing emergency work in connexion with war cases that arrangements have been made by the committee to undertake the following in the matter of fire precautions for the impending winter :—

1. The committee will provide a suitable printed "warning" for posting in wards and rooms, copies of which will be supplied gratuitously on written application.

2. They will arrange for experienced professional men to act as honorary fire surveyors with a view to inspecting hospital buildings and homes, and advising such simple precautions as can be taken without expenditure having to be incurred.
3. They are prepared to provide experienced retired firemen from their Special Fire Service Force to act as watchmen or as fire patrols.

All inquiries should be made to the Registrar, British Fire Prevention Committee, 8, Waterloo-place, London, S.W. The committee have submitted to us a specimen of the "warning," which summarises excellently the precautions to be taken against fire in emergency institutions, as well as the steps to be taken on the occurrence of an outbreak.

MEDICAL CASUALTIES AT THE FRONT.

The following additional casualties to officers of the Royal Army Medical Corps in the Expeditionary Force have been reported:—*Killed:* Lieutenant William Ormsby Wyndham Ball and Lieutenant John Crocket.

SECOND EASTERN GENERAL HOSPITAL, BRIGHTON.—Official notification has been received that no further batches of wounded will be sent from the front to the Second Eastern General Hospital at Brighton, the War Office having decided that the finely-equipped building, which was erected, and used for a few terms only, as a grammar school, shall be devoted in future to the needs of the new army—the men forming the great encampments at Shoreham and Seaford on the Sussex coast, and Crowborough, in north Sussex. The hospital now comprises 520 beds, and this number has to be increased immediately to 800. The building was taken over by the military authorities on August 7th, but it was not until Sept. 1st that the first batch of wounded arrived direct from the battle of Mons. Another batch arrived three weeks later, 580 cases in all being treated. The second and last batch of wounded included many very serious cases, but thanks to the skill of the medical staff, coupled with the work of the fully trained Territorial nurses, only two deaths in all have occurred. The operating theatre has been constantly in use.

THE SECOND WESTERN GENERAL HOSPITAL, MANCHESTER.—The fourth train of wounded soldiers, 122 in all, has reached Manchester. There are now 460 wounded in the Military Hospital in Whitworth-street. There are 34 German prisoner patients. Some of the recovering patients who arrived some 10 or 12 days ago have been removed to the Princess-street Hospital in order to make room for new cases which require immediate surgical treatment.

MANCHESTER DENTAL HOSPITAL AND THE TEETH OF RECRUITS.—The staff of this institution has since the beginning of recruiting rendered most efficient aid to those recruits who were able to satisfy the medical inspectors in every respect but one—viz., as to teeth, which were often insufficient in number or unsatisfactory in condition. The amount of gratuitous work done by the staff is enormous. The attendance of would-be recruits for enlistment numbers over 1000. In 297 cases teeth have been supplied. The average attendance is about 40 per day. The committee of the hospital has been obliged to issue an appeal to the public for money to meet the heavy cost of this work.

THE Council of the National Institute for the Blind have undertaken to help, as far as practicable, all men who lose their sight while serving their country in the present war. Names and addresses of those who desire to avail themselves of this offer should be forwarded to the Secretary-General of the Institute, Great Portland-street, London, W.

THE "WAR BABIES" BRANCH OF THE SOLDIERS' AND SAILORS' FAMILIES ASSOCIATION.—Her Majesty the Queen has intimated her great interest in and approval of the Belfast "War Babies" Branch of the Soldiers' and Sailors' Families Association, which was among the first organisations to be started in the United Kingdom. At the Babies' Club, Divis-street, Belfast, during the past four weeks a large number of the wives resident in Belfast of the soldiers fighting for their country have brought their children—from the age of infancy to 2 years—for advice and direction as to their management. Every case is most carefully investigated, so that no unfair advantage will be taken of the aid given, and the numbers are each week increasing.

THE Royal Sanitary Institute is preparing a list of its members on active service, and the secretary would be glad to be informed of the names of those members and associates who hold commissions or who are serving in the Regular or Territorial Forces, and the name of the corps to which they are attached.

AMERICA AND WAR RELIEF.—130 wounded soldiers were admitted into the American Women's War Relief Fund Hospital, Paignton (Devon), last week. The War Office has appointed Lieutenant-Colonel Robert Cardwell Gunning, R.A.M.C. (retired), to be commandant of the institution.—The American Red Cross ship, with medical men and nurses for the belligerent countries, reached Falmouth last week, and separate units have since proceeded to various parts of the theatre of war.

TO THE RELATIVES OF THE WOUNDED.—Relatives of officers and men are informed by the War Office that arrangements have been made for progress reports as to all sick and wounded who are not progressing favourably to be forwarded regularly from the base to the War Office. These reports will be communicated to the next of kin as soon as possible after receipt. All applications as to the condition of the sick and wounded should be made in the case of officers to the War Office, and in the case of men to the Military Record Offices, and private telegrams should on no account be sent to the headquarters of the army in the field or to military offices or hospitals.

THE CHOLERA CORPS.—We understand from Mr. A. White Robertson that, after correspondence with the War Office and the British Red Cross Society, it has been decided that there is no immediate call for the services of this corps. Medical men and nurses who have applied for special training will therefore be free to accept other appointments.

THE PRISONERS OF WAR BUREAU.—The Press Bureau announces that the Prisoners of War Information Bureau has been instituted, with offices at 49, Wellington-street, Strand, W.C. The primary purpose of the bureau is to keep records of information as regards prisoners of war interned in this country in exchange for information about British prisoners of war interned abroad. The bureau has no information as to British prisoners of war in Germany. Inquiries on this point should be made of the War Office.

THE Belgian newspaper *La Patrie*, published at Bruges on Oct. 3rd, contains an account of the manifestation of sympathy by the Belgian soldiers at the English convent for Mr. Samuel Osborn and the English ambulance party. Mr. Osborn was received with cheers, and Mittrailleur Janssens, who speaks English very well, testified to the devotion of the English people for the Belgians and to the "paternal" care of Mr. Osborn in particular. Mr. Osborn, replying, said: "We English thought it our duty to assist you on the field of battle and to succour the wounded as far as possible. You have kindly spoken of me as your father, and if I regard myself as such I must say that I could not have had better or more patient sons to care for."

GUY'S HOSPITAL MEDICAL AND DENTAL SCHOOLS.—The following scholarships have been awarded:—Senior science scholarships for university students: £75, John Maurice Hardman Campbell, New College, Oxford; £35, Frederick Alfred Unwin, King's College, London. Junior science scholarships: £120, Albert Ernest Sawday, Guy's Hospital Preliminary Science Class; £50, Sydney Anselm Sharpe, Guy's Hospital Preliminary Science Class. Entrance scholarships in arts: £50, Edward Emile Delisle Gray, St. Paul's School; £50, Myles Wheeler O'Bryen, Oratory School, Edgbaston. Open scholarship in dental mechanics: £20, Alfred Herbert Bowes. Scholarship in dental mechanics for pupils of Guy's Hospital: £20, Wyndham Brookes Farrington.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—The diploma of L.R.C.P. and M.R.C.S. was conferred upon the following candidates at a special examination held on account of the war on Sept. 24th :—

Hallowes Lloyd Addison, King's College Hospital; Charles Layton Balkwill, Birmingham University; Lancelot White Barlow, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Stanley Batchelor, London Hospital; Tremlett Brewer Batchelor, M.A. Oxon., Oxford University and London Hospital; John Dorrington Batt, Oxford University and St. Bartholomew's Hospital; Lindsay Willett Batten, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Kenneth Benson Bellwood, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; George Albert Berkeley-Cole, Durham and Leeds Universities; Kenneth Biggs, London Hospital; William McHutchison Binning, University College Hospital; Zaki Mikhail Bishara, Cairo and London Hospital; William Herbert Blakemore, Manchester University; Majorie Ada Blandy, Royal Free Hospital; William Houston Boyd, Queen's University, Belfast; James Jackson Brown, London Hospital; Owen Deane Brownfield, St. Thomas's Hospital; Frank Bocquet Bull, L.D.S. Eng., Guy's Hospital; Bruce Burnside, B.A. Cantab., Cambridge University and Guy's Hospital; Lyle John Cameron, M.D. Manitoba, Manitoba University and London Hospital; George D'Rastricke Carr, B.A. Cantab., Cambridge University and London Hospital; Eric Catford, St. Bartholomew's Hospital; Paulin Roger Coevreau, Guy's Hospital; George Frederick Clifton, B.A. Cantab., Cambridge University and University College Hospital; John Stanley Cocks, L.D.S. Eng., Guy's Hospital; William Tregonwell Collier, B.A. Oxon., Oxford University and University College Hospital; William John Cook, M.D., C.M. McGill, McGill University and London Hospital; Lionel Palliser Costobadie, Cambridge University and London Hospital; Richard Irving Dacre, Bristol University; John Horace Dancy, St. George's Hospital; Thomas William David, Cardiff and St. Bartholomew's Hospital; Percy Vernon Davies Charing Cross Hospital; Marcelline de Costa, Ceylon Medical College and Guy's Hospital; Edmund Rupert Dermer, Middlesex Hospital; Mostafa Dia, Cairo and St. Mary's Hospital; Stephen Ormond Dolan, Leeds University; Alexander John D'Souza, L.M.S. Madras, Madras and Middlesex Hospital; Harold Dunkerley, Cambridge University and London Hospital; James Angel Durante, London Hospital; Mohamed Kamil El Kholy, Cairo and University College Hospital; Richard Feltrim Fagan, University College Hospital; Frederick Ernest Feilden, Middlesex Hospital; Hassell Dyer Field, St. Thomas's Hospital; Robert Ovens Fisher, M.B. Toronto, Toronto University and Middlesex Hospital; John Edward Foley, Birmingham University; Edward Dance Fountain, St. Mary's Hospital; Hugo Rudolph Friedlander, St. Thomas's Hospital; Cassidy de Wet Gibb, Guy's Hospital; Gerald Francis Petvin Gibbon, St. Bartholomew's Hospital; Edward Harold Hertslet Granger, B.A. Cantab., Cambridge University and University College Hospital; George Leonard Grant, B.A. Cantab., Cambridge University and London Hospital; Alan Renata Green, M.B., Ch.B. New Zealand, Otago University and London Hospital; Samuel Lionel Green, St. Bartholomew's Hospital; Ernest Richard Gordon Greville, St. Thomas's Hospital; Ernest Frederick Guy, University College Hospital; Norah Hamill, Royal Free Hospital; Ernest Eugene Herga, London Hospital; Arthur Edward Huxtable, Charing Cross Hospital; Laurence Mansfield Ingle, B.A. Cantab., Cambridge University and London Hospital; Rupert William Percival Jackson, B.A. Cantab., Cambridge University and Guy's Hospital; Charles Evans Jenkins, Cardiff and London Hospital; Rosalie Jobson, Royal Free Hospital; Samuel Walter Maslen Jones, Middlesex Hospital; Sydney Hudson Keys, Middlesex Hospital; Gerald Patrick Kidd, St. Thomas's Hospital; Noel Sigismund Koch, St. Bartholomew's Hospital; Gajanan Chintaman Kusumbeker, L.M.S Bombay, Bombay University and London Hospital; Francis Claud Lapage, Cambridge University and Middlesex Hospital; Robert Ancel Leembruggen, Ceylon Medical College and St. Bartholomew's Hospital; Arthur Baker Le Mesurier, M.B. Toronto, Toronto University; Kingsley Wassell Lewis, University College Hospital; James Arthur Liley, London Hospital; Andrew Hunter Little, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Iorwerth Hubert Lloyd-Williams, Middlesex Hospital; Edward Richardson Lovell, Middlesex Hospital; Henry Dundas McCall, B.A Cantab, Cambridge University and St. Bartholomew's Hospital; Francis Oreti MacGibbon, New Zealand and London Hospital; Roderic MacGill, Manchester University; Helen Marion Macpherson Mackay, Royal Free Hospital; Alan Samuel Lack Malcolm, B A. Cantab., Cambridge University and University College Hospital; Edith Marjorie Martland, Royal Free Hospital; Claude Jocelyn Delabere May, Bristol University; Henry Leslie Messenger, L.D.S. Eng., Guy's Hospital; Vaman Raghunath Mirajkar, L.M.S. Bombay, Bombay University and St. Bartholomew's Hospital; Leonard William Mortimer, London Hospital; Arthur Rennie Muir, Cardiff and University College Hospital; Wilfrid Davison Newcomb, B.A. Cantab., Cambridge University and London Hospital; George Marshall Oakden, L.D.S. Eng., Sheffield University and Middlesex Hospital; Guy William Parry, St. Bartholomew's Hospital; Henry Ray Parsloe, London Hospital; Margaret Russell Paterson, Royal Free Hospital; John Ernest Pearce, St. Bartholomew's Hospital; Charles Harry Grenville Penny, L.D.S. Eng., Guy's Hospital; Michael Gladstone Pettigrew, Sheffield University and University College Hospital; Leonard Robert Pickett, L.D.S. Eng., Guy's Hospital; Emma Christine Pillman, Royal Free Hospital; John Pinder, Leeds University; John Alexander Pridham, St. Bartholomew's Hospital; Grantly Dick Read, B.A. Cantab., Cambridge University and London Hospital; Frederick Tavinor Rees, Cardiff and St. Bartholomew's Hospital; Henry Charles Cadell Rennie, M.B., B.S. Adelaide, Adelaide University and London Hospital; Adrian St. Johnston, Cambridge University and St. Thomas's Hospital; Eric Arthur Langford Sansom, University College Hospital; William Goodman Shakespeare, Westminster Hospital; John Patrick Shaw, Middlesex Hospital; Reginald Hugh Simpson, St. Bartholomew's Hospital; Bawa Harkishan Singh, Lahore and Middlesex Hospital; Herbert Smith, Birmingham University; Cecil Spurling Staddon, St. Thomas's Hospital; Edwin Cyril Widmerpoole Starling, B.A. Cantab., Cambridge University and Guy's Hospital; Frank Sykes, Leeds University; Leonard Hankinson Terry, St. Bartholomew's Hospital; George Robert Seager Thomas, B.A. Cantab., Cambridge University and Westminster Hospital; Pensam Thornton, Birmingham University; Naomi Tribe, Royal Free Hospital; Geoffrey Say Trower, Cambridge University and St. Bartholomew's Hospital; Bryan Montague Tuke, Middlesex Hospital; Jocelyn Langton Waller, St. Mary's Hospital; Eric Watson-Williams, B.A. Cantab., Cambridge University and King's College Hospital; Gervas Charles Wells-Cole, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Leslie Herbert Worthy Williams, Cardiff and University College Hospital; and Maurice Ulick Wilson, King's College and Westminster Hospital.

At the Second Professional Examination in Anatomy and Physiology held on Sept. 24th, 25th, 27th, and 28th, for which 62 candidates presented themselves, of whom 43 were approved and 19 were rejected, the following were approved :—

Kenneth Norman Grierson Bailey and Thomas Burton Bailey, St. Bartholomew's Hospital; Herbert Frederic Gustave Berncastle, Guy's Hospital; Kalyanpur Harikar Bhat, Madras University and Charing Cross Hospital; Butros Bishara, Cairo and St. Mary's Hospital; Leslie Graham Blackmore, Middlesex Hospital; Charles James Longworth Blair, St. Bartholomew's Hospital; James Bassett Brash, St. Bartholomew's Hospital; Albert William Abell Davies, Guy's Hospital; Frederick Graham Leslie Dawson, London Hospital; Saad el Din Ahmed El Daab, Cairo and Dublin; Abdel Aziz Hassan El-Zeneiny, Cairo and London Hospital; John Harold Ewen, St. Mary's Hospital; Edwin Francis Fernando, University College; John Turnbull Thomson Forbes, Otago and Guy's Hospital; Arthur Reginald Hart, King's College; Mahdy Sayed Hashish, Cairo and St. Bartholomew's Hospital; Thomas Lowthian Heath, Guy's Hospital; Henry Saumarez Hensman, L.M.S. Madras, Madras Medical College; Eric Blanford Hickson, University College; Stewart Russell Johnston, University College; Ganapathy Mallya, L.M.S. Madras, Madras Medical College; Reginald Stanley Millar, Durham University and Guy's Hospital; Anis Mishriky, St. Mary's Hospital; Bireswar Mitra, L.M.S. Calcutta, Calcutta Medical College; Vijaya Shankar Rao Pandit, Bombay University; Walter Davies Pearman, St. Mary's Hospital; Arthur Winifred Peeris, University College; Walter Erichsen Powell, Charing Cross Hospital and King's College; Hubert Llewellyn Pridham, St. Bartholomew's Hospital; Raghavandra Rau, Madras Medical College and Middlesex Hospital; Rupert Idris Rhys, Arthur Rodd, and Herbert Henry Silley, University College; Maurice Oliver Simpson, Middlesex Hospital: Robert Sydney Steele Smith, St. Bartholomew's Hospital; Vincent Russell Smith, St. Mary's Hospital; Eric Lionel Stephenson, London Hospital; Arthur Anton Thiel, St. Bartholomew's Hospital; Edward Sherman Toogood, B.A Oxon., Oxford University; Shankarlal Kunvarji Vaidya, L.M.S. Bombay, Bombay University and London Hospital; Leonard Heatley Woods, St. Bartholomew's Hospital; and William Yeoman, University College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the First Professional Examination for the Licence in Dental Surgery held on Sept. 24th, 25th, and 26th, the following candidates were approved in the subjects indicated :—

Mechanical Dentistry and Dental Metallurgy.—John Gordon Ackland Royal Dental Hospital; Geoffrey Walter Allen and Alfred Herbert Bowes, Guy's Hospital; Norman Henry Davey, Leeds University; Frederick Knowles Escritt, Wyndham Brookes Farrington, Edward Garratt Foulston, Philip Green, Douglas Brigstocke Hitchings, Charles Henry Kidner, and Harold Octavius Long, Guy's Hospital; Albert Victor Milton and Robert Orton, Leeds University; Stanley James Peatfield, Guy's Hospital; Enoch Sanders, Liverpool University; Cyril Wells Spendelow, Royal Dental Hospital; Arnold Clough Sutcliffe, Leeds University; Ian Murray Thomson, Guy's Hospital; Edward Francis Vowles, Bristol University; and Maurice Harold Wermig, Guy's Hospital.

Mechanical Dentistry.—Norman John Ainsworth, Royal Dental Hospital; Harry Edward Attkins, National Dental Hospital; Herbert Joseph Barrand, Guy's Hospital; Frederick David Blomfield, National Dental Hospital; Arthur Bowler, Liverpool University; Ellis Gardner Browne and Charles Reginald Cade, Guy's Hospital; Reginald George Joseph Charlesworth and Neville George Compton, Royal Dental Hospital; James Frank Cowell, Liverpool University; James Walter Curtis, Royal Dental Hospital; Stanley Willoughby Augustus Davis, Bristol University; Robert Peter Dewar, London Hospital; Lionel Harold Dixon, Guy's Hospital; Frank Leslie Hooton Fox, Bristol and Guy's Hospital; Robert William Fyffe and Leonard Wilfred Hearn, Sheffield University; Gerald Mackenzie Hickley, Royal Dental Hospital; Oswald Octavius Lloyd, Llewellyn Arwyn Morris, Frank Douglas Neal, and Arthur Llewellyn Payne, Guy's Hospital: John Peter, Royal Dental Hospital; Stanley Edwin Pomeroy, London Hospital; Beresford Tom Richards, Birmingham University; John Cowan Robertson and Simon Sanders, Guy's Hospital; Robert Ferdinand Sievers, Royal Dental Hospital; Norman Leslie Smallbone, London Hospital; Charles Herbert Davenport Smith, Royal

Dental Hospital; Cecil Stanley Southwell, Guy's Hospital; Mansfield John Knox Soutter, National Dental Hospital; Rodney Frederick Jarrett Sterwin, London Hospital; Eleanor Cannell Watterson, National Dental Hospital; and Leonard Gould Whelpton, Guy's Hospital.

Dental Metallurgy.—Barrington Eady and Jenkin Albert Evans, Guy's Hospital; Morgan James Evans, Birmingham University; George Frederick Faustmann, Guy's Hospital; Blanche Sutton Gardner, National Dental Hospital; Alice Dora Headley and Harold Awbery Hill, Birmingham University; William Grant Milton, Bristol University; John Rhys Morgan, Liverpool University; Henry Montgomery Scott Pillow, Guy's Hospital; David Maurice Rees and Valentine Sainty, Royal Dental Hospital; Hugh Muir Smith and Percival Albert Tucker, Guy's Hospital; Sorab Byramji Warden, M.B., B.S. Bombay, Bombay University and Royal Dental Hospital; and Claude Young, Royal Dental Hospital.

“Bacilli and Bullets.”—Sir William Osler's recent address to the officers and men in the camps at Churton has now been issued as a penny pamphlet, entitled “Bacilli and Bullets,” by the Oxford University Press.

A West Country Centenarian.—Mrs. Mary Ann Saunders died last week at Yatton, Somersetshire. She celebrated the 103rd anniversary of her birthday on July 8th last.

St. George's Hospital Medical School.—The Entrance Scholarships in Anatomy and Physiology, of the value of 70 guineas and £50, have been awarded to R. Salisbury Woods, of Downing College, Cambridge, and J. A. Birrell, of the University of Wales respectively.

Westminster Hospital Medical School.—The following awards of scholarships have been made: Guthrie scholarship in arts (£60), J. G. Wilson, Colfe Grammar School, Lewisham; natural science (£60), E. S. Davies, University College, London; anatomy and physiology (£50), N. M. Lewis, Cardiff Medical School.

West London Post-Graduate College.—The autumn session will begin on Monday next, Oct. 12th, at the West London Hospital, Hammersmith-road, W. The practice of this general hospital is reserved for post-graduate students attached to the college. Full information may be obtained from the dean of the college, Mr. Donald Armour.

New Professor of Anatomy at St. Andrews University.—Professor David Waterston, M.A., M.D., C.M. Edin., has been appointed to succeed Professor J. Musgrove in the Bute chair of anatomy in the United College of the University of St. Andrews. Professor Waterston leaves King's College, London, where he has been professor of anatomy.

London Hospital Medical College (University of London).—The following are the results of the Entrance Scholarships:—Price Entrance Scholarship in Science, £100, I. H. Zortman; Price Entrance Scholarship in Anatomy and Physiology for students of the Universities of Oxford and Cambridge, £52 10s., H. D. McIlroy (Jesus College, Cambridge).

Scarlet Fever in Belfast.—During the period embraced between August 16th and Sept. 12th last, 147 cases of scarlet fever were notified, the total number of infectious diseases notified being 187; those in addition to scarlet fever recorded are 15 of diphtheria, 9 of typhoid fever, and 16 of erysipelas. The ordinary public health measures—notification, isolation, hospital treatment, and disinfection—have had no effect whatever in diminishing the occurrence of scarlet fever in Belfast. For the same period the death-rate from all causes was 18·7, while from zymotic diseases it was 5·5, and from chest affections, 4·5.

A Periodical for Lost Refugees.—With the authorisation of the Belgian Minister, Count de Lalaing, a paper, called *L'Echo de Belgique*, is published weekly at 43, Palace-street, London, S.W. The object is to assist the Belgian refugees in this country by giving them, in French and Flemish, a brief summary of the week's news, but, above all, by providing a means of intercommunication. In the flight from their bombarded or destroyed towns and villages members of the same family were often separated from each other. Populations scattered in all directions are now longing to come together again, to discover who has escaped, and to communicate with one another. The first issue of the paper contains several hundred names of refugees who want to know what has become of their nearest friends and relations. Of course, this publication is not a commercial speculation. It is distributed gratuitously among the refugees, and no charge is made for inserting their appeals and inquiries. Those, however, who can afford to buy the paper will assist the work of relief by helping to keep the publication going.

Death of a Medical Veteran.—The death is announced at Audley, in Staffordshire, of Dr. Richard Vernon, in his ninety-eighth year. He qualified L.S.A. in 1846 and obtained the M.D. degree of the University of Glasgow in the same year. For 20 years he was medical officer of health of Audley.

Presentation to a Medical Practitioner.—At the annual distribution of awards to the members of the Falmouth division of the St. John Ambulance Brigade, Dr. Charles Robert Browne was presented with a pair of spurs as a mark of appreciation for his services as honorary instructor, and to congratulate him on his recent appointment as major in the R.A.M.C. (T.F.)

Pharmaceutical Society.—The seventy-third session of the School of Pharmacy of the Pharmaceutical Society was opened on Sept. 30th, when an address was delivered in the lecture theatre at 17, Bloomsbury-square, London, W.C., by Dr. Lauriston E. Shaw. Dr. A. W. Crossley, F.R.S., has resigned the professorship of chemistry at the school, having been appointed to the chair of organic chemistry at King's College, University of London. Professor Henry L. Smith, formerly lecturer in chemistry at King's College, London, and in applied chemistry at King's College for Women, has succeeded Professor Crossley in the Pharmaceutical Society's chair of chemistry.

Literary Intelligence.—Messrs. J. and A. Churchill announce for autumn publication the following new books:—“The Anatomy of the Human Skeleton,” by J. Ernest S. Frazer, F.R.C.S. Eng., lecturer on anatomy at St. Mary's Hospital Medical School (with 219 illustrations); “Medical Diagnosis,” by Arthur Latham, M.D. Oxon., F.R.C.P. Lond., physician and lecturer on medicine at St. George's Hospital, and J. A. Torrens, M.B., B.S. Lond., M.R.C.P. Lond., assistant physician to St. George's Hospital (with about 100 illustrations); and “The Chemistry of Cyanogen Compounds and their Manufacture and Estimation,” by Herbert E. Williams.

Royal Dental Hospital of London, School of Dental Surgery.—On account of the war the dinner for past and present students announced to be held on Nov. 21st will not take place this year. Sir Charles Wyndham will distribute the prizes next year instead of this year, as previously arranged. The prizes for this year will be distributed by the chairman of the managing committee, Mr. Arthur Hood, on Nov. 17th, at 5.30 P.M. No formal invitations will be issued, but old students and friends will be welcome. The post-graduate lectures announced for October and November will be postponed, but may be given in the New Year if circumstances permit.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Alexander, R. Charles, F.R.C.S. Edin., has been appointed Temporary Assistant Surgeon to the Royal Infirmary, Edinburgh.

Carlow, Walter W., F.R.C.S. Edin., has been appointed Temporary Assistant Surgeon to the Royal Infirmary, Edinburgh.

Dolan, Charles, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Dispensary Medical Officer for Ballinamore, County Cavan.

Evans, D. A., L.R.C.P & S. Edin., L.F.P.S. Glasg., has been appointed House Surgeon at the Herefordshire General Hospital.

Graham, James M., F.R.C.S. Edin., has been appointed Temporary Assistant Surgeon to the Royal Infirmary, Edinburgh.

Jardine, Frank E., F.R.C.S. Edin., has been appointed Temporary Assistant Surgeon to the Royal Infirmary, Edinburgh.

McGrath, P., L.R.C.P. & S. Irel., D.P.H., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Ardagh District of the county of Limerick.

Ritchie, J., M.D., C.M. Aberd., D.P.H., has been appointed Medical Officer for the Buchan Combination Poorhouse, Maud.

Webb, C. C., M.B., B.C. Cantab., D.P.H., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Yatton District of the county of Somerset.

Wood, Walter Q., M.B., Ch.B. Edin., has been appointed Temporary Assistant Surgeon to the Royal Infirmary, Edinburgh.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (*see Index*).

Ashton-under-Lyne District Infirmary and Children's Hospital.—Senior House Surgeon. Salary £140 per annum, with board, residence, and laundry.

Belgrave Hospital for Children, Clapham-road, S.W.—Resident Medical Officer for six months. Salary at rate of £100 per annum, with board, residence, and washing.

Birkenhead Borough Hospital.—Junior House Surgeon. Salary £100 per annum, with board and laundry.

Birmingham City Asylum, Rubery-hill.—Junior Assistant Medical Officer. Salary £200 per annum, with apartments, board, laundry, &c.

Birmingham Union.—Dudley-road Infirmary: Third Assistant Medical Officer and Fourth Assistant Medical Officer. Salary at rate of £180 and £160 per annum respectively. Erdington Infirmary and Cottage Homes: Assistant Medical Officer. Salary at rate of £200 per annum. Selly Oak Infirmary: Assistant Medical Officer. Salary at rate of £180 per annum. Apartments, rations, laundry, and attendance in each case.

Birmingham, Yardley-road Sanatorium and Anti-Tuberculosis Centre.—Third Assistant Medical Officer. Salary £200 per annum, with board and residence.

Bolton Infirmary and Dispensary.—Second House Surgeon. Salary £120 per annum, with apartments, board, and attendance.

Bootle Borough Hospital.—Junior House Surgeon. Salary £100 per annum, with residence, board, and laundry.

Bournemouth, Royal Victoria and West Hants Hospital.—House Surgeon, unmarried, for six months. Salary £100 per annum and extras, with board, lodging and washing.

Brighton County Borough Asylum, Haywards Heath.—Temporary Resident Assistant Medical Officer. Salary £5 5*s*. a week.

Bristol City Asylum, Fishponds.—Second Assistant Medical Officer, unmarried. Salary £250 per annum, with apartments, board, washing, and attendance.

Bristol, Cossham Memorial Hospital, Kingswood.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

Bristol General Hospital.—First House Physician, Second House Physician, House Surgeon, and Casualty House Surgeon for six months. Salary at rate of £120 per annum, with board, residence, &c.

Bristol Royal Infirmary.—House Surgeon and House Physician for six months. Salary at rate of not less than £100 per annum, with board, apartments, and laundry.

Bury St. Edmunds, West Suffolk General Hospital.—Resident Medical Officer, unmarried. Salary £160 per annum, with board, lodging, and laundry.

Camberwell Infirmary, Brunswick-square, Camberwell.—Assistant Medical Officer. Salary £190 per annum. Also Assistant Medical Officer for six months for Infirmary, Brunswick-square, Camberwell, and Gordon-road Institution, Peckham. Salary at rate of £200 per annum. Apartments, board, and washing in each case.

Cancer Hospital, Fulham-road, S.W.—Surgical Registrar. Salary £100 per annum.

Canterbury, Kent County Asylum, Chartham.—Junior Assistant Third Medical Officer, unmarried. Salary £250 per annum, with quarters, board, washing, &c.

Cardiff City Mental Hospital, Whitchurch, near Cardiff.—Second Assistant Medical Officer, unmarried. Salary £280 per annum and all found.

Central London Throat and Ear Hospital, Gray's Inn-road, W.C.—Registrar.

Cheddleton, Leek, Staffordshire County Mental Hospital.—Assistant Medical Officer. Salary £270 per annum, with quarters, board, attendance, and washing.

Chesterfield and North Derbyshire Hospital.—Senior House Surgeon. Salary £140 per annum, with board, apartments, and laundry.

Chichester, Royal West Sussex Hospital.—House Surgeon, unmarried. Salary £110 per annum, with board, residence, and washing.

City of Westminster Union Infirmary, Fulham-road, S.W.—Second Assistant Medical Officer and Third Assistant Medical Officer. Salaries £160 and £140 per annum respectively, with board, residence, and washing.

Derby, Derbyshire Hospital for Sick Children.—Female Resident Medical Officer. Salary £100 per annum.

Durham County Hospital.—House Surgeon. Salary £150 per annum, with board, residence, and laundry.

Great Yarmouth Hospital.—House Surgeon, unmarried. Salary £140 per annum, with board, lodging, and washing.

Hackney Union Infirmary, High-street, Homerton, N.E.—Two Junior Assistant Medical Officers. Salaries £170 per annum, with rations, apartments, and attendance.

Halifax Royal Infirmary.—Second and Third House Surgeons, both unmarried. Salaries £120 and £100 per annum respectively, with residence, board, and washing.

Hartlepool, Hartlepools Hospital.—House Surgeon. Salary £125 per annum, with board, washing, and lodging.

Hospital for Consumption and Diseases of the Chest, Brompton.—House Physician for six months. Salary £5 5*s*. per month.

Huddersfield Royal Infirmary.—Assistant House Surgeon. Salary £80 per annum, with board, rooms, and washing.

Hull Royal Infirmary.—Senior House Surgeon, unmarried. Salary £150 per annum, with board and apartments. Also Assistant House Surgeon. Salary at rate of £100 per annum, with board and lodging.

Leeds Public Dispensary.—Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry.

Leicestershire and Rutland Mental Hospital, Narborough, near Leicester.—Junior Medical Officer. Salary £200 per annum, with board, lodging, and washing.

Liverpool. Royal Southern Hospital.—House Physician and House Surgeon for six months. Salary at rate of £60 per annum, with board and residence.

London Throat Hospital, 204, Great Portland-street, W.—House Surgeon. Salary £50 per annum.

Manchester, City of.—Assistant Tuberculosis Officer. Salary £350 per annum.

Manchester Education Committee.—Female Assistant School Medical Officer. Salary £300 per annum.

Manchester, Hulme Dispensary, Dale-street, Stretford-road.—House Surgeon. Salary £180 per annum, with apartments, attendance, coal, and gas.

Manchester, Monsall Fever Hospital.—First Medical Assistant. Salary £225 per annum, with board, lodging, and washing

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

Manchester Royal Eye Hospital.—Junior House Surgeon. Salary £80 per annum, with residence, board, and washing.

Margate, Royal Sea Bathing Hospital for Surgical Tuberculosis.—Resident Surgeon. Salary at rate of £150 per annum, with board, residence, and laundry.

Metropolitan Hospital, Kingsland-road, N.E.—Temporary Assistant Surgeon.

Middlesbrough, North Ormesby Hospital.—House Surgeon. Salary £120 per annum, with board, apartments, washing, and attendance.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Resident Medical Officer. Also Junior House Surgeon for six months. Salaries £150 and £85 per annum respectively, with board, residence, and laundry.

Mount Vernon Hospital for Consumption and Diseases of the Chest.—Assistant Physician.

Newcastle-upon-Tyne City Asylum, Gosforth.—Locum Tenens Assistant Medical Officer.

Newcastle-upon-Tyne Hospital for Sick Children.—Senior Medical Officer and Junior Medical Officer for six months. Salary £100 and £80 per annum respectively, with board, lodging, and laundry.

Newport (Mon.). Royal Gwent Hospital.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

Northampton County Asylum, Berry Wood.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

Nottingham City Education Committee.—Third Medical Inspector. Salary £300 per annum.

Nottingham General Hospital.—Assistant House Physician and Assistant House Surgeon for six months. Salary at rate of £100 per annum each, with board, residence, and laundry. Also Senior House Physician. Salary £120 per annum, with board, residence, and laundry.

Otago University, New Zealand.—Professor of Clinical Pathology. Salary £600 per annum.

Portsmouth Royal Hospital.—House Surgeon for six months. Salary £90 per annum, with board, &c.

Preston Royal Infirmary.—Assistant Resident Medical and Surgical Officer. Salary £120 per annum, with board, residence, and laundry.

Putney Hospital, Putney Common, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and laundry.

Ramsgate General Hospital and Dispensary.—Resident House Surgeon, unmarried. Salary £120 per annum, with board, residence, and laundry.

Reading, Berkshire Education Committee.—Assistant Medical Inspector of Schools. Salary £300 per annum.

Reading, Royal Berkshire Hospital.—House Surgeon, House Physician, and Second House Surgeon for six months. Salary each £100 per annum, with apartments, board, and washing.

Rotherham Hospital.—Assistant House Surgeon. Salary £110 per annum, with board, lodging, and washing.

Royal Free Hospital, Gray's Inn-road, W.C.—Male and Female House Physicians and House Surgeons for six months. Also Junior Obstetric Assistant for six months. Board, lodging, and washing provided in each case. Also Two Acting Assistant Surgeons for out-patients. Also Female Assistant Anæsthetist for six months. Salary £75 per annum.

Royal Waterloo Hospital for Children and Women, S.E.—Junior Resident Medical Officer. Salary at rate of £70 per annum, with board and washing.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—Radiographer, part time only. Salary 25 guineas per annum. Also House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and laundry. Also Assistant House Surgeon. Salary (non-resident) £20 for six months, with part board.

Ryde, Royal Isle of Wight County Hospital.—Resident House Surgeon, unmarried. Salary £115 per annum.

St. George's Hospital.—Two House Surgeons for six months. Board and residence provided.

St. Mary's Hospital for Women and Children, Plaistow, E.—Female Resident Medical Officer and Female Assistant Resident Medical Officer. Salary at rate of £110 and £90 per annum respectively, with board, residence, and laundry.

St. Pancras Dispensary, 39, Oakley-square, N.W.—Resident Medical Officer, unmarried. Salary £105 per annum, with residence and attendance.

Salford Royal Hospital.—Resident Surgical Officer and Casualty House Surgeon for six months. Salary at rate of £120 and £100 per annum respectively, with board and residence.

Salisbury (General) Infirmary.—Assistant House Surgeon, unmarried. Salary £75 per annum, with apartments, board, lodging, and washing.

Sheffield Children's Hospital.—House Surgeon. Salary £150 per annum, with board and residence. Also House Surgeon at East End Hospital (Out-patient Department only). Salary £120 per annum, with board and residence.

SHEFFIELD ROYAL INFIRMARY.—Two House Surgeons and Assistant House Physician for six months. Salary £100 per annum each, with board and residence.

SOUTHAMPTON FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £115 per annum, with residence, board, and washing.

SUNDERLAND COUNTY BOROUGH EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £300 per annum.

SUNDERLAND ROYAL INFIRMARY.—Junior House Surgeon. Salary £100 per annum, with board, residence, and laundry.

SWANSEA UNION.—Resident Assistant Medical Officer. Salary about £295 per annum.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Senior House Surgeon and Assistant House Surgeon. Salaries £120 and £80 per annum respectively, with board, lodging, and laundry.

TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with rooms, board, and washing.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.—Assistant Resident Medical Officer, unmarried. Salary £100 per annum, with board, lodging, &c.

WAKEFIELD, WEST RIDING ASYLUM.—Assistant Medical Officer. Salary £200 per annum, with apartments, board, washing, and attendance. Also Locum Tenens Assistant Medical Officer. Salary as arranged, with apartments, board, and travelling expenses.

WALSALL AND DISTRICT HOSPITAL.—Junior House Surgeon and Anæsthetist. Salary £110 per annum, with board, residence, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Rowfant, in the county of Sussex; and at Stanford-le-Hope, in the county of Essex.

New Addresses.

GASKELL, J. F., M.D., The Uplands, Great Shelford, Cambridge.

A fee of 2s. 6d. is charged for the insertion of Notices of Change of Address, which must not exceed two lines.

Births, Marriages, and Deaths.

BIRTHS.

BALLANCE.—On Oct. 2nd, at Selwyn-gardens, Cambridge, the wife of Hamilton A. Ballance, M.S. Lond., of Norwich, of a daughter.

BROOKS.—At Stanway-gardens, Ealing Common, W., to Dr. and Mrs. Ralph St. John Brooks, a son.

PARKHURST.—On Oct. 2nd, at Rathan, Newhaven, the wife of Rodie Parkhurst, M.B., C.M., of a son.

MARRIAGES.

LEE—McNAB.—On Sept. 30th, at Murrayfield-gardens, Edinburgh, Alaister Fraser Lee, M.D., R.A.M.C.T., Lieutenant Highland Mounted Brigade Field Ambulance, to Minnie, second daughter of the late Mr. John McNab, and of Mrs. McNab, Seacraig, Nairn.

PRIDEAUX—THOMAS.—On Sept. 29th, at St. Mary Magdalene, Loders, Bridport, Dorset, Charles Sydney Prideaux, L.D.S. R.C.S. Eng., to Adeline Irene, eldest daughter of the Rev. David and Mrs. Thomas, of The Vicarage, Loders.

DEATHS.

LITTLEJOHN.—On Sept. 30th, at Benreoch, Arrochar, Sir Henry Duncan Littlejohn, M.D., in his 87th year.

O'CONNELL.—On Sept. 20th, killed in action at the Battle of the Aisne, Lieutenant John Forbes O'Connell, M.B., B.S. Lond., R.A.M.C., aged 25 years.

PILGRIM.—On Oct. 1st, at Brighton, suddenly, Lieutenant-Colonel Herbert Wilson Pilgrim, M.B., F.R.C.S. Eng., Indian Medical Service (retired), aged 56 years.

SHAW.—While on a visit to Bournemouth, Harold Bailey Shaw, M.B., B.A., aged 55, Medical Superintendent of the Isle of Wight County Asylum.

VASSIE.—On Oct. 2nd, at Crofton Hill, Lanark, Mary Janet Spears, wife of Alex. H. Vassie, M.B., C.M., 98, Priory-road, London, N.W., only child of the late William Roy Spears, Solicitor and Town Clerk of Kirkcaldy. (No flowers.)

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

During the continuance of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

BRITISH REGIMENTAL HOSPITALS IN 1799.

IN the year 1799 there was issued from the Horse Guards in London, "By Order of His Royal Highness the Commander in Chief," by Harry Calvert, Adjutant General, a small handbook of "Regulations from the Army Medical Board to Regimental Surgeons," &c. This little book has come into our possession. On p. 18 the "Duties of the Surgeon" are set out as follows: "It is necessary that every Surgeon of the regular forces, militia, supplementary militia, or fencible corps, whether he receives allowances from government for furnishing Hospital, Hospital bedding, serjeant, nurse, orderlies, medicines, materials, &c., or whether he is furnished with the same by government, shall keep in his possession, ready for immediate use, a sufficient quantity of the best medicines and materials, according to the Army Dispensatory No. 2.—An invoice for a full Regimental Chest, calculated for 1000 men, is also added, No. 3. He is likewise to be always in possession of a complete set of instruments for regimental Hospitals, provided at his own expence, agreeable to the annexed list, No. 4. A list of a field set, for more immediate and actual service, is also subjoined, No. 5." The following is a copy of the list No. 4, referred to: "A Compleat Set of Instruments, with Modern Improvements, for Regimental Hospitals. An Amputating Saw, with spare Blade; 1 Metacarpal Saw, with ditto; 24 Curved Needles; 2 Amputating Knives; 1 Catlin; 2 Tenaculems; 1 Bullet Forceps; 1 Pair of Bone Nippers; 2 Screw Tourniquets; 4 Field Tourniquets with Handle; 2 Callico Compresses; 2 Trephines, with sliding Keys; 1 Trephine Forceps; 1 Elevator; 1 Lanticular; a Brush; Key Instruments for Teeth, to fit Trephine Handle; 8 Scalpels; 2 Silver Catheters; 1 Trocar with Spring and introductory Canula; 1 Ditto, ditto, and Canula for Hydrocele; 1 Probang; 1 Long Silver Probe; 1 Large Bougie." The following is a copy of List No. 5, and the surgeon who used the book has inscribed in faint pencil the prices of the instruments:—"A Compleat Set of Instruments for the Field, with the Modern Improvements. An Amputating Saw, £1 1*s.*; 1 Metacarpal Saw, 7*s.* 6*d.*; 12 Curved Needles, 6*s.*; 1 Amputating Knife, 7*s.*; 1 Catlin, 3*s.* 6*d.*; 1 Screw Tourniquet, 10*s.* 6*d.*; 1 Silver Catheter, 8*s.*; 1 Elastic ditto, 9*s.*; 2 Trephines, to fit one Handle, £2 2*s.*; 1 Trephine Forceps, 5*s.*; 1 Elevator, 3*s.* 6*d.*; 2 Scalpels, 4*s.*; 1 Bullet Forceps, 5*s.*; 1 Trocar with Spring & introductory Canula, 14*s.*; 1 Trocar with Spring Canula for Hydrocele, 5*s.*; a Brush, 1*s.*; A Tenaculem, 1*s.* 6*d.*; Thread for Ligatures, 1*s.*" To these he has added in pencil, "case" £1 15*s.*, and he makes the total £9 17*s.* The Regulations say that: "A Regiment consisting of 1000 men, and provided with three medical persons, ought to be furnished with Hospital necessaries and utensils for at least forty patients, forty cotton night-caps, forty sets of bedding, in the proportion of four for every hundred men; each set consisting of one palliass, one straw mattrass, one bolster, three sheets, two blankets, and one rug. Each Hospital ought to be furnished with a slipper bath, or bathing tub, two water buckets, one dozen of Oznaburgh towels, one dozen of flannel cloths, half a dozen of large sponges, combs, razors, and soap, two large kettles, capable of making soup for 30 men, two large tea kettles, two large tea pots, two sauce-pans, forty tin cans of one pint each, forty spoons, one dozen of knives and forks, two close-stools, two bed-pans, and two urinals."

THE WISDOM OF ANIMALS.

To the Editor of THE LANCET.

SIR,—In respect to the universal aversion of cats for water noticed in THE LANCET of Sept. 26th, I may mention an incident which came under my own observation last month. Standing on a bridge carrying a road over a "drain" in Romney Marsh I noticed a cat on one of the wooden supports just preparing to spring at something, probably a vole, in the water below. The cat was about 2 ft. above the water, and the aim for the spring was about a yard away, among some weeds. Suddenly the splash came; there was some struggling, and then the cat scrambled back to the bank, soaking wet, without its prey. The expression of exasperation on its face was human; the look it gave me as it passed was one of such anger as to suggest at once lurid language. Just before disappearing it turned round and glared at me, as if to relieve itself of some of its feelings, and as if to say, "You —— bounder, it was you who spoilt my sport." But I was merely a spectator.—I am, Sir, yours faithfully,

Oct. 5th, 1914. PERCY DUNN.

CENTIGRADE AND FAHRENHEIT.

To the Editor of THE LANCET.

SIR,—An easy way of remembering how to convert degrees Centigrade into degrees Fahrenheit and *vice versa* is supplied by the mem. tech. "See far enough at thirty-two" (C. Fahr. n/f add 32), where $\frac{n}{f}$ stands for 9 over 5. If you want to go back—i.e., from F. to C., go back, simply changing the signs as you go. Thus, subtract 32, multiply by 5, divide by 9. The whole formula may be briefly represented thus:—

"SEE FAR ENOUGH AT THIRTY-TWO
<——————————————."

My explanation is, perhaps, somewhat cumbersome, but the formula once understood is quite difficult to forget.

I am, Sir, yours faithfully,

Brompton, S.W., Oct. 1st, 1914. F. A. HORT.

*** The ordinary formula, for comparison, is $\frac{C. \times 9}{5} + 32 = F.$ —ED. L.

PROPRIETARY MEDICINES IN THE FAR EAST.

REPORTING on the trade of the district of Osaka, Japan, for the year 1913 Mr. Oswald White, the British Vice-Consul, observes that a flourishing little business is done in proprietary medicines, of which China took in 1913 £117,000 worth from Osaka and Kobe. They are mostly in the form of pills, which claim to be specific against most of the minor ills of life. The Japanese themselves consume considerable quantities and sales in China appear to be growing.

PERKINS'S TRACTORS.

To the Editor of THE LANCET.

SIR,—Perhaps some more details concerning Perkins and his Tractors may be of interest to your readers.[1] This subject was dealt with fully in 1842 by Oliver Wendell Holmes in two lectures delivered in Boston on "Homœopathy and its Kindred Delusions." The following is the account which Holmes gave of the inventor:—

"Dr. Elisha Perkins was born at Norwich, Connecticut, in the year 1740" (not 1745 as stated in THE LANCET). "He had practised his profession with a good local reputation for many years, when he fell upon a course of experiments, as it is related, which led to his great discovery. He conceived the idea that metallic substances might have the effect of removing diseases, if applied in a certain manner; a notion probably suggested by the then recent experiments of Galvani, in which muscular contractions were found to be produced by the contact of two metals with the living fibre. It was in 1796 that his discovery was promulgated in the shape of the *Metallic Tractors*, two pieces of metal, one apparently iron and the other brass, about three inches long, blunt at one end and pointed at the other. These instruments were applied for the cure of different complaints, as rheumatism, local pains, inflammations and even tumours, by drawing them over the affected part very lightly for about twenty minutes. Dr. Perkins took out a patent for his discovery, and travelled about the country to diffuse the new practice. He soon found numerous advocates of his discovery, many of them of high standing and influence. In the year 1798, the tractors had crossed the Atlantic and were publicly employed in the Royal Hospital at Copenhagen. About the same time the son of the inventor, Mr. Benjamin Douglass Perkins, carried them to London, where they soon attracted attention. The Danish physicians published an account of their cases, containing numerous instances of alleged success, in a respectable octavo volume. In the year 1804, an establishment, honoured with the name of the Perkinean Institution, was founded in London. The transactions of this institution were published in pamphlets, the Perkinean Society had public dinners at the Crown and Anchor, and a poet celebrated their medical triumph. ...... While all these things were going on Mr. Benjamin Douglass Perkins was calmly pocketing money, so that after some half a dozen years he left the country with more than ten thousand pounds, which had been paid him by the believers in Great Britain. But ...... Perkinism soon began to decline, and in 1811 the tractors are spoken of by an intelligent writer as being almost forgotten."

"Terrible Tractoration" (which was referred to in your note) "is supposed," says the Autocrat, "by those who never read it, to be a satire upon the follies of Perkins and his followers. It is, on the contrary, a most zealous defence of Perkinism, and a fierce attack upon its opponents, most especially upon such of the medical profession as treated the subject with neglect or ridicule."

It is at least some satisfaction to learn that the Connecticut Medical Society expelled Perkins in 1797 for violating their law against the use of nostrums or secret remedies.

I am, Sir, yours faithfully,

E. MUIRHEAD LITTLE.

Seymour-street, W., Oct. 1st, 1914.

FOOD ECONOMY.

THE great war and its probable effect sooner or later on the national food-supply should surely bring home to the nation the importance of economy and of husbanding resources. It is undoubtedly true that very many of us habitually eat too much food, often of the wrong kind, and prepared in the least physiologically useful manner, and that a large amount of foodstuff is continuously wasted. Some intertesting notes on these and kindred subjects, such as the rise in prices, a pure milk-supply, bread and breadmaking, meals for under-nourished scholars, and institutional and school diet, are to be found in the Sixth Annual Report of the National Food Reform Association, published at 178, St. Stephen's House, Westminster, price 6*d*.

AN AUTUMN CRUISE TO MOROCCO.

THE Royal Mail Steam Packet Company announce an autumn cruise to Morocco, the Canary Islands, and Madeira by the *Arzila*, which has been appointed to sail from London in about a fortnight's time. The cruise will last 23 days and include calls at Gibraltar, the ports of Tangier, Casablanca, Mazagan, Saffi, and Mogador in Morocco, and the islands of Las Palmas, Teneriffe, and Madeira. The charge for the round trip is £18.

THE Globe-Wernicke Company, Limited, are anxious to correct the impression which may exist that their company is connected with German interests in any way whatsoever. They state that it is an all British concern with English proprietors and employing only British labour. The word "Wernicke" in the title is due to the fact that many years ago they purchased the patent rights of their "elastic" bookcases from the inventor, a Mr. Wernicke, an American born citizen, and they also purchased the right to use his name which was associated with these patents. Mr. Wernicke is not connected in any way with the company, which has never imported or sold German furniture.

Mr. N. H. Graesser writes as follows: As there is apparently some doubt in regard to the origin of many of the Cresol disinfectants now being offered, I have pleasure in informing you that "Acrosyl" is made throughout at my works at Ruabon, North Wales, by British labour and British capital.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Thursday.

Section of Dermatology (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 p.m.

Cases:

Dr. J. H. Sequeira: (1) Sarcoids; (2) Myxo-sarcoma.
Dr. H. C. Samuel: Xerodermia Pigmentosa in an Adult.
Dr. S. E. Dore: Multiple Soft Fibromata.
And other Cases.

Friday.

Section of Electro-Therapeutics (Hon. Secretaries—S. Gilbert Scott, E. P. Cumberbatch): at 8.30 p.m.

Discussion:

On the Localisation of Foreign Bodies (including bullets, &c.) by X-rays, to be opened by Sir James Mackenzie Davidson, M.B. (illustrated by means of skiagrams, &c.).

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

Monday.—8 p.m., General Meeting. 8.30 p.m., Introductory Address by the President (Sir John Bland Sutton).

SOCIETY FOR THE STUDY OF INEBRIETY, Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.

Tuesday.—3.30 p.m., Council Meeting. 4 p.m., Discussion on Drug Addiction in Relation to Mental Disorder (opened by Dr. R. Armstrong-Jones).

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

Wednesday.—8.30 p.m., Council Meeting. 9 p.m., Hunterian Society Lecture:—Sir Dyce Duckworth, Bart.: The Patient and the Disease.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

Wednesday—9 p.m, Dr. A. Whitfield: Lichen Planus, its Varieties and Treatment. (Lantern Demonstration.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Museum Demonstrations for Advanced Students and Medical Practitioners:—

Friday.—5 p.m., Prof. A. Keith: Specimens illustrating Gunshot Injuries of the Head—Ancient and Modern.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

Monday.—10 a.m., Dr. Simson: Diseases of Women. 10.30 a.m., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Eye Department. 5 p.m., Lecture.

Tuesday.—10 a.m., Dr. Robinson: Gynæcological Operations. Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 p.m., Lecture.

Wednesday.—10 a.m., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 a.m. Mr. Souttar: Demonstration of Minor Operations. 12 noon Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye. 5 p.m., Lecture.

Thursday.—9 a.m., Dr. Bernstein: Bacterial Therapy Department. 10 a.m., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye. 5 p.m., Lecture.

Friday.–10 a.m., Dr. Robinson: Gynæcological Operations. 10.30 a.m., Surgical Registrar: Demonstration of Cases in Wards. 12.15 p.m., Lecture:—Dr. Bernstein: Applied Pathology. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin. 5 p.m., Lecture.

Saturday.—10 a.m., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 12 noon, Lecture:—Mr. Souttar: Surgical Anatomy of the Abdomen. 2 p.m., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

Tuesday.—3.30 p.m., Lecture:—Dr. F. E. Batten: Clinical Cases.
Friday.—3.30 p.m., Clinical Lecture:—Dr. G. Stewart: Localisation of Cerebellar Tumours.

THE THROAT HOSPITAL, Golden-square, W.

Monday.—5.15 p.m., Special Demonstration of Selected Cases.
Thursday.—5.15 p.m., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

Tuesday.—4 p.m., Dr. J. L. Bunch: Salvarsan and Syphilis.
Thursday.—6 p.m., Chesterfield Lecture:—Dr. M. Dockrell: Baldness and its Treatment.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

Thursday.—Ancoats Hospital, Mill street.—4.30 p.m., Dr. D. E. Core: Disseminated Sclerosis.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editor," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT [illegible] REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Colonial and Foreign Edition (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from The Lancet Offices, have been reduced, and are now as follows:—

For the United Kingdom.				To the Colonies and Abroad.			
One Year	£1	1	0	One Year	£1	5	0

THE LANCET, OCTOBER 17, 1914.

The Presidential Address

ON

CANCER OF THE DUODENUM AND SMALL INTESTINES.

Delivered before the Medical Society of London on Oct. 12th, 1914,

BY SIR JOHN BLAND-SUTTON, F.R.C.S. ENG., LL.D.,

SURGEON TO THE MIDDLESEX HOSPITAL.

GENTLEMEN,—The distribution of cancer in the section of the alimentary canal known as the gastro-intestinal tract is remarkable. Cancer is very common in the stomach, but in the intestine between the pylorus and the ileo-cæcal valve it is uncommon. Primary cancer is rare in any part of the small intestine, but it occurs more frequently in the duodenum, short as it is, than in the jejunum or the ileum.

CANCER OF THE DUODENUM.

A study of the effects produced by cancer of the duodenum shows that the time-honoured division of this section of the small intestine into first, second, and third parts is of little use for the purposes of clinical medicine. It is more convenient, following Sherren, to call the portion above the bile papilla the supra-ampullary segment, the portion containing the bile papilla the ampullary, and the remainder the infra-ampullary segment.

Supra-ampullary Cancer.

Duodenal ulcer is a common affection, and observations made on the living in the course of operation and on the dead have shown that the ulcer, for it is nearly always solitary, occurs most frequently in that section of the duodenum immediately adjacent to the pylorus. The chronic indurated duodenal ulcer is usually situated in the first 2 cm. of the duodenum, and four-fifths of the patients are men.

Many surgeons who have had great experience in gastric surgery believe that a chronic ulcer of the stomach is a precancerous condition. There is much evidence to support the view that a chronic gastric ulcer, like a chronic ulcer of the leg, a lupus patch, or a chronic syphilitic ulcer of the tongue, occasionally becomes cancerous. All admit the difficulty of early diagnosis in cancer of the alimentary canal from the pylorus downwards; the disease furnishes no sign until it becomes septic or obstructs the lumen of the gut. This explains our great ignorance of the early stages of cancer arising in the stomach, duodenum, and on through the intestine to the anus. It is insisted by some surgeons that if chronic gastric ulcers are liable to become cancerous the same changes should affect chronic duodenal ulcers. Observations teach that cancer of the duodenum is a rare disease, and there is no evidence that it arises in a chronic duodenal ulcer. Malignant disease of the duodenum of any kind is uncommon, and few specimens of cancer of the small intestine are preserved in the hospital museums in London. This is sufficient to indicate not only that the disease is uncommon, but the important fact that a cancer of the duodenum is rarely excised by surgeons. The only example of malignant disease in the supra-ampullary section of the duodenum I have seen associated with a chronic duodenal ulcer was a sarcoma. A man, aged 55, had well-marked symptoms of pyloric obstruction, and at the operation a polypoid mass could be felt in the duodenum and was easily pressed into the pyloric ring. There was a well-marked scar on the serous surface of the duodenum opposite the pylorus. I resected the pylorus with the adjacent part of the stomach and the duodenum to within half an inch of the bile papilla. The duodenum was closed and the stomach also. Union of stomach and small intestine was re-established by a posterior gastro-jejunostomy. The parts exsected show a fungating growth springing from the floor of the chronic ulcer. Microscopically it is a spindle-celled sarcoma.

The post-operative course of this case is of some interest. A few days after the operation the duodenal stump leaked, and much bile-stained fluid escaped through the lower angle of the abdominal incision. Frequently the fluid was quite clear, alkaline, and excoriated the skin. This fluid was mainly pancreatic juice, and in a few days the patient was in the condition of Pawlow's famous dog. This animal had an artificial pancreatic fistula, and the escaping fluid eroded the skin. The dog was tied up in the laboratory and at night scraped the plaster from the wall and lay with its belly in the débris. This suggested a plan of treatment, and a bed of sand was prepared for the clever dog, and the pancreatic juice no longer eroded the skin. I did not give my patient a bed of sand, but the erosion of the skin was prevented by covering the skin surrounding the fistula with gauze or lint soaked in paroleine.

A perusal of Pawlow's experimental observations helped me a great deal in the management of my patient. We know the average amount of fluid secreted daily by important organs, such as the liver, kidneys, and stomach, but no one has determined the average amount of fluid secreted by the pancreas, because the pancreatic secretion varies in quantity with the nature of the food. The greatest stimulant is fat. In my patient there were times when the fluid flowed in an almost continuous stream and quite clear. This happened when he swallowed milk. A fat-free dietary was then arranged, consisting of whey, beef-tea from which fat was carefully removed, water, and tea. The fistula soon closed. It was unfortunate that after piloting the patient through many difficulties he died a month after operation with apparently an abdominal dissemination of the disease. The man being a Jew his relatives refused a post-mortem examination.

Circum-ampullary Cancer.

Cancer arising in the duodenal mucous membrane around the bile papilla is known as circum-ampullary cancer, in order to distinguish it from cancer arising in the ampulla or in the common bile-duct, but the three varieties lead to obstruction of the bile-duct, jaundice, and distension of the gall-bladder. There can be little doubt that cancer of this section of the duodenum would often escape detection if it were not for the obstruction it offers to the flow of bile from the common duct. It is very difficult to distinguish clinically between circum-ampullary cancer, ampullary cancer, and malignant disease of the head of the pancreas, for all give rise to obstructive jaundice often associated with an over-distended gall-bladder.

Cancer of the Ampulla.

From a practical standpoint the distinction between cancer arising in the mucous membrane

No. 4755]

of the duodenum near the ampulla and cancer arising in the ampulla may not be important, but primary cancer of the ampulla is interesting in itself and exhibits some remarkable peculiarities. Nowhere in the body does so small a growth lead to such grave interference with digestion. A cancerous growth, sometimes no larger than a cherry, will block the outflow of bile and pancreatic juice, and cause intense jaundice and great emaciation by interfering with digestion in consequence of the obstruction to the outflow of pancreatic juice. The three clinical signs of cancer of the ampulla are painlessness, intense jaundice, and great emaciation. The pathological features of the disease are its slight tendency to infiltrate surrounding structures, the infrequency of dissemination, and the enormous dilatation of the main bile-ducts and the gall-bladder. A feature of cancer of the ampulla which distinguishes it from cancer of the gall-bladder is the infrequency with which it is associated with gall-stones. In spite of the local nature of the disease it quickly destroys life. When cancer of the ampulla has caused jaundice death usually follows within six months.

The daring resourcefulness of modern surgery is well exemplified in the attempts to deal with this singular form of cancer, and there can be little doubt that some means will be found for dealing with it successfully. Some valuable papers have been written on this subject by Hartmann, Körte, Schuler, Kausch, and Upcott. An American surgeon, Outerbridge, has recently collected 100 reported cases.

Very few specimens of ampullary cancer have been described in London, and there are few specimens in the metropolitan museums. Perhaps it is only necessary to draw attention to this deficiency in order to have it remedied.

Cancer of the Transverse or Infra-ampullary Duodenum.

This is the common place for duodenal cancer. The symptoms associated with it are like those set up by cancer of the pylorus, but the vomited matter contains bile and pancreatic juice and is sometimes very offensive. The cancer is usually of the constricting type, and the duodenum above the constriction becomes enormously distended. The dilated stomach and duodenum constricted by the pylorus resemble a bilocular stomach. Cancer sometimes arises in the middle of the transverse portion of the duodenum, and the growth involves the vena cava and the superior mesenteric vessels. A constricting cancer in this part of the duodenum may be so hidden as not to be visible until the gut is opened. Rolleston has seen the channel of the gut so narrowed that its lumen in the cancerous section would only admit the passage of a pencil.

I had an opportunity of operating on a man in whom the duodenum was completely obstructed by cancer. The patient, aged 56, was invalided from Burma on account of persistent vomiting and rapid emaciation. Cancer of the stomach seemed to be the most probable cause of the illness, but no lump could be felt in the stomach or its neighbourhood. The vomiting resembled that seen in the condition known as a "vicious circle" after gastro-jejunostomy; it was very offensive. At the operation the stomach was found to be contracted, and on turning it over to examine the posterior surface I found a small contracting growth in the middle of the third part of the duodenum. This hard ring of cancer completely obstructed the gut, so that the bile and pancreatic juice regurgitated into the stomach, where they mingled with the gastric juice and ingested fluids to be ejected as filthy vomit. The duodenum above the stricture was enormously dilated and produced an appearance like a bilocular stomach. The cancer had involved the walls of the duodenum and implicated the superior mesenteric vein; excision of the affected area of the gut was impracticable. Posterior gastro-jejunostomy was performed, and the distended section of the duodenum was also anastomosed with an adjacent coil of jejunum. The vomiting ceased after the operation, and the patient began to take food freely and assimilate it. Pain ceased, and we hoped that his life might be prolonged. Cardiac dyspnœa began to cause trouble, circulatory complications arose, and he died 14 days after the operation. A post-mortem examination confirmed the opinion, formed at the time of the operation, in regard to the impracticability of removing the cancerous portion of the intestine, for it involved the pancreas extensively as well as the large blood-vessels.

In the infra-ampullary cases the vomit always contains bile and pancreatic juice; this is of diagnostic value. Pancreatic juice can be demonstrated by the digestion of fibrin in the filtered vomit, with the addition of a few grains of bicarbonate of soda.

CANCER OF THE JEJUNUM AND ILEUM.

Tumours of the jejunum and ileum are interesting pathologically and clinically. A tumour of any kind in the small intestine is rare, and those belonging to the benign group are, as a rule, pedunculated; the propulsive movements of the intestine not only affect the contents, but influence tumour formations within its walls. The simple tumours arising in the intestinal walls may be lipomas, some are described as myomas, and many as sarcomas, but whatever the structure the constant propulsive efforts of the intestine tend to force the tumour towards the lumen of the bowel until it projects within it covered merely by a layer of mucous membrane. The danger to be feared from such a tumour is invagination, or intussusception, of the gut, for the tumour, acting as a foreign body, is urged along the bowel, and being fixed to the bowel wall drags it in and produces an intussusception which, if unrelieved by art or the timely sloughing of the intussusceptum, ends in fatal obstruction.

The peristalsis of the small intestine probably exercises moulding effects on deposits of cancer within its walls as well as on benign tumours; this applies to secondary as well as primary deposits. A man with disseminated melanoma was admitted into the Middlesex Hospital with intestinal obstruction. In the face of widespread melanomatous deposits an operation for the relief of the obstruction was regarded as useless; to the astonishment of the physician the symptoms abated and the patient passed a long slough of intestine which proved to be a piece of ileum containing a deposit of melanoma. This had led to intussusception, and the intussuscepted piece of gut sloughed and the man recovered.

The museum of the London Hospital contains a portion of ileum in a state of intussusception caused by a secondary deposit of melanocarcinoma. The specimen was obtained from a woman admitted with signs of strangulated femoral hernia; at the operation the supposed hernia proved to be an enlarged lymph-node charged with black pigment. The woman died, and the invaginated gut was discovered after death. The seat of the primary growth is not stated.

CANCER AND ACCESSORY PANCREATIC TISSUE.

A consideration of tumours of the small intestine would be incomplete without reference to the suggestion that cancer of the small intestine may arise in an accessory pancreas. Small detached masses of pancreatic tissue have been detected in the stomach near the pylorus and in the duodenum; they may be situated in the mucosa, the muscularis mucosæ, or in the muscular layer of the intestine, and measure 3 or 4 cm. in diameter. An accessory pancreas is occasionally situated at the apex of a diverticulum. Although such diverticula usually arise in the duodenum, they have been observed in the lower parts of the ileum and regarded as persistent Meckelian diverticula. A pancreatic and a Meckelian diverticulum have been found in the same individual. It is possible that pancreatic diverticula are produced by traction; they are by no means harmless, and several cases have been reported in which a diverticulum, with a pancreas at its apex, has invaginated into the bowel and produced intussusception. In a remarkable case reported by O'Connor an inverted diverticulum caused intussusception in a boy aged 13. On the fourth day after the attack he passed 11¼ inches of gangrenous intestine with the diverticulum attached.

It is necessary to mention accessory pancreas when considering cancer of the duodenum and small intestine, because those pathologists who still believe that cancer arises in embryonic vestiges think it probable that this perversion may arise in islands of pancreatic tissue. There is no evidence to support this theory, nor that which attributes duodenal cancer to morbid changes in Brunner's glands. Like the theory attributing parotid chondromas to relics of Meckel's cartilage, they belong to the domain of fiction. Such theories indicate that some pathologists, like poets, are not devoid of imagination.

CANCER AT THE END OF THE ILEUM.

The frequency of ulcer and cancer at the pylorus is not repeated at the ileo-cæcal valve. This part of the small intestine, notwithstanding its narrowness, is rarely attacked by morbid growths, and they have been rarely the subject of critical analysis. For many years I have been interested in this question and find obstructive growths at the valve are of four kinds: (1) cancer arising in the ileum; (2) cancer arising in the cæcum; (3) malignant growths in the vermiform appendix; and (4) hyperplastic tubercle of the ileum.

Cancer at the ileo-cæcal junction, in the cases I have seen, has been of the circular contracting type and leads to almost complete occlusion of the opening. The contraction is so extreme that it is necessary to make a careful search in order to detect it, and as a rule the disease is more easily felt than seen. It is a remarkable thing that such inconspicuous growths give rise to widespread metastasis in the abdomen. For example, an elderly woman had a large ovarian cyst associated with frequent vomiting, two conditions forming a sinister combination and suggestive of malignant disease of the bowel associated with the ovarian cyst. The removal of the cysts—there were two, one as big as the patient's head and the other the size of a turkey's egg—was easily accomplished, but the presence of much solid matter in the walls of the cyst convinced me that the solid matter was implanted cancer. The distended condition of the small intestines led me to search carefully for an obstruction, and I found a thin, narrow, hard ring of growth completely obliterating the ileo-cæcal orifice. The ileum was joined to the ascending colon by a lateral anastomosis. The woman survived and lived free from pain and able to look after her house for 12 months. In this instance the primary lesion, though contracting and atrophic, had shed cancerous cells into the general peritoneal cavity which had fallen on the walls of the ovarian cysts and converted them into solid cancerous masses.

The frequency with which ovaries and ovarian cysts are converted into solid blocks of cancer by the implantation of cells shed from a primary focus in the gastro-intestinal tract is not properly appreciated by gynæcologists, but I am glad to note that the number of converts is steadily increasing, and my scepticism in the existence of primary cancer of the ovary is intensified by further experience.

Cancer arising in the cæcum does not obstruct the lumen of the bowel at such an early stage as when it arises in the colon, but there is an anatomical arrangement by which cancer arising in the cæcum can obstruct the ileum. The terminal two inches of the ileum rests in close contact with the wall of the cæcum; if cancer or hyperplastic tubercle attacks the mucous membrane of the cæcum immediately in relation with the terminal portion of the ileum, the intermediate tissues become infiltrated with growth, the walls of the ileum are implicated, and ultimately its lumen becomes obstructed.

A study of the specimens of primary cancer of the small intestine preserved in the hospital museums in London shows that the disease presents the same characters as in the colon. Some are of the annular contracting type, constricting the gut as if a piece of cord had been tightly tied around it. In others the disease sprouts like a cauliflower into the bowel; there is a massive form which envelops the intestine with a hard collar of new growth. An annular constricting cancer strictly limited to the ileal aspect of the ileo-cæcal valve is associated with signs of intestinal obstruction, rendering accurate localisation of the obstruction a matter of uncertainty. There is nothing in the signs and symptoms approaching the definiteness characteristic of a constricting cancer of the third part of the duodenum.

The chief feature connected with cancer of the gastro-intestinal tract is its extreme frequency at the pylorus and its rarity at the ileo-cæcal valve. The age distribution of cancer of the small intestine agrees with that of the stomach and colon.

PRIMARY MALIGNANT DISEASE OF THE APPENDIX.

In order to show the difficulty of properly assessing the frequency of cancer at the ileo-cæcal valve the following case is useful:—

A man, aged 73, came under observation with symptoms of chronic intestinal obstruction, and a lump was easily detected in the region of the cæcum. It was freely movable and painless. The age of the patient, the absence of fever and tenderness, the presence of a movable swelling in the right iliac fossa, accompanied with intestinal stasis and vomiting, indicated that the mass was in all probability a cancerous growth in the cæcum.

This view being confirmed in the course of the operation, I excised the cæcum and joined the ileum by an end-to-side anastomosis in the ascending colon. The patient died suddenly six days after the operation.

The cæcum and exsected portion of the ileum were preserved, and on subsequent examination the mass proved to be a primary tumour of the vermiform appendix which had infiltrated the adjacent walls of the ileum and cæcum, including the segments of the valve. Microscopically the growth possesses the features of a sarcoma. There were no signs of dissemination, and no enlarged lymph-nodes were detected. Such growths in the appendix are probably rare.

HYPERPLASTIC TUBERCULOUS AFFECTIONS IN THE NEIGHBOURHOOD OF THE VALVE.

An analysis of the various growths which arise at the ileo-cæcal junction makes it evident that some of the tumours in this situation labelled after operation cancer are in some instances tuberculous. The hyperplastic form of intestinal tuberculosis is most common in the cæcum and cæcal end of the ileum. It differs from other varieties of tuberculous disease in that the lesion is not destructive and leads to an increase in the bulk of the part affected. The disease begins in the submucous or subserous tissue and spreads to the other coats of the bowel. The new tissue contains clumps of giant-cells and sometimes calcareous deposits. Occasionally the thickened bowel is enveloped in a mass of fibro-fatty tissue such as sometimes surrounds chronic tuberculous kidneys. The cavity of the bowel is narrowed, sometimes a track no larger than a writing-quill remains, and the ileo-cæcal valve is obstructed; in rare cases the disease is limited to the valve. This condition is very liable on mere naked-eye examination to be mistaken for cancer of the ileum or cæcum, and it is very probable that some cases in which the cæcum has been excised for a tumour casually regarded as cancer and the patients have remained free from recurrence the disease was really hyperplastic tuberculous disease.

From the operative point of view the distinction between cancer and hyperplastic tubercle is not important because the treatment for both conditions is the same—excision, but is a matter of great concern in regard to prognosis. Cancer and hyperplastic tubercle left to run their course end fatally, but the latter is curable by excision. Hyperplastic tubercle of the bowel was not recognised till 1891; then it received attention from Billroth, Hartmann, and Pilliet. Very little attention has been given to the disease in Britain, although there is reason to believe that tuberculous disease attacks the cæcum more frequently than any other part of the gastro-intestinal tract.

MELANOSIS OF THE COLON.

Melanosis is a morbid condition of the mucous membrane of the colon that has received little attention in Great Britain. My experience is limited to one example.

A septuagenarian spinster had suffered from recurring attacks of intestinal obstruction. At last colostomy was necessary, and a constricting annular cancer was excised from the iliac colon. Four months later the cut ends of the bowel were rejoined successfully. The mucous membrane of the excised portion of the gut was of an inky blackness, but the cancer in the bowel had the microscopic structure common to primary cancer of the colon and was devoid of pigment. The blackness of the mucous membrane depended on a deposit of pigment in the connective tissue of the mucosa.

I am unable to state how much of the colon was pigmented because the patient recovered from her operation, but I examined her thoroughly with the object of finding evidence of a melanoma or an ulcerated pigmented wart, but found none. This pigmentation of the colon puzzled me. During the Christmas vacation, 1912, I visited the museum at Friedrichshain, Berlin. There I saw a colon with the same deep pigmentation. The intense blackness affected the colon uniformly, being sharply limited above the ileo-cæcal valve and extending thence to the anus. The terminal portion of the vermiform appendix was obliterated, but the mucous membrane of its proximal unobliterated part shares in the pigmentation.

Professor Dr. Ludwig Pick has discussed in an exhaustive manner the anatomical, histological, and chemical features of this rare form of pigmentation. He also gives a useful summary of nearly a score of similar cases, beginning with one recorded by Virchow (1847) and three described in England by C. J. Williams (1867), G. Newton Pitt (1891), and H. D. Rolleston (1892). Pick states that the colouration is not due to metallic deposit; it is essentially a pigmentation of the connective tissues of the mucous membrane and hæmatogenous.

Although the pigmentation begins, as a rule, at the ileo-cæcal valve and extends to the anus, cases have been observed in which it does not involve the whole length of the colon. When the colic membrane is involved throughout the pigmentation is discoverable at the anus by means of a speculum. The condition is mainly a clinical curiosity, but if detected in the course of a clinical examination it might have an undue significance attached to it. It will be useful to have some further observations on this curious pigmentation.

CONCLUSION.

I selected cancer of the small intestine as the subject of the address this evening because it is a matter neglected in the ordinary works on surgery. It is intended to hold a discussion at our next meeting on the Surgery of Tumours of the Large Intestine, and we hope to have an exhibition of illustrative specimens of tumours of the small intestine as well as tumours of the cæcum and colon. The council is hopeful that a series of specimens illustrating hyperplastic tuberculous disease of the cæcum will be shown. This disease, often mistaken for cancer of the cæcum, has not, as already mentioned, received much attention in this country, although Henri Hartmann made it the subject of the oration in 1911. The society will also be grateful for the loan of specimens illustrating primary cancer of the vermiform appendix, a disease concerning which there is much uncertainty. It will also be useful to obtain some further observations on the curious pigmentation of the colon.

CARDIFF MEDICAL SCHOOL.—At the last meeting of the council of the University College of South Wales it was stated that the anonymous benefactor, whose offer of a large sum for the building of the new medical school at Cardiff was accepted early this year (*vide* THE LANCET, Feb. 21st, 1914, p. 568), had since promised a further sum of £10,000 towards the building fund of the medical school.

Introductory Address

ON

THE POSITION OF PSYCHIATRY AND THE RÔLE OF GENERAL HOSPITALS IN ITS IMPROVEMENT.

Delivered at the Opening of the Winter Session, 1914–15, at the Middlesex Hospital on Oct. 1st, 1914,

BY C. HUBERT BOND, D.Sc., M.D. EDIN., M.R.C.P. LOND.,

COMMISSIONER OF THE BOARD OF CONTROL AND EMERITUS LECTURER IN PSYCHIATRY AT MIDDLESEX HOSPITAL MEDICAL SCHOOL.

GENTLEMEN,—In the first place I desire to express my thanks to the council of the medical school for the honour they have done me in asking me to give the introductory address which is customary at the opening of each of our winter sessions. That I particularly esteem the privilege will be readily appreciated when I remind you of where we are gathered, and that this is the first function which has taken place in the Bland-Sutton Institute of Pathology, which, with its laboratory, lecture theatre, and museum, will always be a monument to Sir John Bland-Sutton's princely munificence, to his affection for the hospital and medical school, to his devotion to science, and to his belief in her power to relieve suffering humanity. And who will dare attempt to gauge the direct and indirect influence of this institute? Sir John's catholicity is well known, and I feel assured of his sympathy when I venture to hope that psychiatry, which is the branch of medicine in which my interests are specially centred, will have its fair share of the blessings that doubtless will be showered from this institute.

The pleasure of our gathering is, however, marred in one particular, for we have to lament the absence of His Serene Highness, Prince Alexander of Teck, whose active interest in all that pertains to the welfare of the hospital and medical school is so deeply appreciated, and whose presence we should have enjoyed to-day were it not that his military duties have made it impossible.

Few academic sessions can ever have opened amidst such momentous events as does the present one; and whatever diffidence I felt in accepting the responsibility of this year's address has not been diminished by the fact that I am conscious there are other members of the school's staff who would in all likelihood have chosen a theme more in consonance with the stirring events with which our thoughts are thrilled: indeed, realising that such a course would probably prove the more acceptable, I did make an attempt to recast the draft of my remarks; but, not unmindful of Pliny's injunction to the cobbler and wishing to eschew anything like an "ultracrepidarian" reputation, I have harked back to my original purpose, which was to bring before your notice (A) the present position in which psychiatry stands; (B) the essential cause of this position; and (C) to endeavour to convince you that general hospitals—more particularly those to which medical schools are attached—can, if they choose, effect a material improvement therein.

(A)—PSYCHIATRY THE CINDERELLA OF MEDICINE.

Psychiatry, or by whatever other term you prefer to denote the study and treatment of mental diseases, has sometimes been characterised as the Cinderella of general medicine; that is to say, it has been alleged to be a branch (first) which, compared with other medical subjects, lacks sustaining interest, and (secondly) whose study is apt to side-track its devotees into blind alleys, where their scientific enthusiasm is chilled and their legitimate aspirations to maintain an honourable position for themselves are disappointed. Now while I can emphatically assert that any such description is a very one-sided one, and wholly untrue as respects the first part of the allegation, there is in its second part a modicum of truth, which has, I believe, barred the way to many a young medical man who would otherwise have maintained his initial interest in the subject both to its and his own advantage, and which therefore had better be clearly understood.

(a) *Wherein the Statement is not True.*

To refute the allegation that the study of psychiatry in any way lacks sustaining interest is not difficult. What student or medical man, possessed of his normal share of scientific inquisitiveness, has ever filled a resident post in an institution for the insane in which, affiliated to a medical school, teaching and research work go hand in hand with its administration, and has come away imbued with any such notion? I have never met him. On the contrary, if really necessary, it would be an easy task to demonstrate that the subject possesses an absorbing and, indeed, transcendent interest; that in its compass—not easy to define—its borders insensibly merge into those of other departments of general medicine; that in not a single medical or surgical case can the mental side of the patient be safely ignored; that the truth of this last fact—often forgotten—not infrequently comes home to the medical man in attendance with startling and unpleasant force; that without a sound knowledge of at least the elements of psychiatry such circumstances may cause him much embarrassment; and, lastly, that, to the medical man who is tempted to dive below the mere surface of the subject, there is a wealth of problems, each well deserving a life's devotion, whose non-solution impedes successful treatment, but whose elucidation may with confidence be expected to restore to a normal life many of those afflicted with the direst of human calamities, who, in the light, or rather the obscurity, of existing knowledge, are now too often doomed to premature death or life-long segregation from their friends. And, of still greater moment to the public, there is good ground for believing that, with the removal of some of the perplexities with which the subject is at present strewn, not only will many a man and woman be able to ward off the necessity of such segregation, but also will the path of many a one be rendered smooth where now, by reason of the traveller's neuropathic oddities and obsessions, it is thorny and often pursued only at a cost of much mental pain. The accomplishment of all this by no means spells a fresh goal. The problems which now await solution are, for the most part, fresh hill-points which have come into view when the summit of others has been attained by the indefatigable labours of certain of our predecessors and *confrères* in the specialty. That they have been all too few and often ill requited is true enough, but in their accumulated observations they have left a heritage which is a veritable treasure house. In no other branch of medicine is the harvest whiter than in psychiatry, and I fain would persuade some of you who are about to enter the medical profession to come in and gather it.

(b) *The Allegation True in Two Counts.*

Wherein then, you will ask, is psychiatry even remotely deserving to be dubbed a Cinderella? The epithet is deserved, I fear, as respects two counts: (1) The unpopularity of the asylum medical service; and (2) the manner in which psychiatry's claims are overlooked by philanthropists. Both are, in my opinion, dependent primarily on the same cause.

1. *The unpopularity of medical work in asylums.*—The first and probably most obvious count is the undeniable reluctance of young medical men and women either to enter the specialty at all, or, if they do join it, to do so with a view to applying themselves seriously to it as their life's work. Certain it is that at the present moment public asylums—even those most favourably situated—find it increasingly hard to obtain suitable candidates from which to fill vacancies in the junior ranks of their medical staffs; so acute has been the difficulty that, at a large asylum in a medical staff comprising a superintendent and six assistants, I have known as many as three of the latter positions filled at the same time by locum-tenents—in other words, by men between whom and the institution the link is so small that it can be severed at a week's notice. No one will deny that such a position of affairs is a menace to the present and future welfare of any such institution; it is highly desirable that it should be realised by the public in whose hands, mainly through their municipal representatives, the remedy largely lies.

(*i.*) *Causes of this unpopularity.*—The task of exposing and grappling with the difficulty has within the last three years been undertaken by a committee of the Medico-Psychological Association, and is set forth in an admirable and comprehensive report which will be found in this month's number of the *Journal of Mental Science*. This report is all the more weighty, and should the more recommend itself to the public, by reason of the fact that nowhere are the interests of the patients subordinated to those of the medical men; and because, with the pecuniary advancements claimed for some of the latter, there is *pari passu* a demand for increased opportunities for adequate initial training and future study and research. The subject is also dealt with at some length in the Sixty-eighth Report (pp. 40, 41) of the Commissioners in Lunacy, which was published this year. No doubt the paucity of applications for these by no means unimportant and not ill-paid asylum posts is to some extent due to the large increase in the number of available public health appointments (whether as medical officers of health, school medical officers, or tuberculosis officers), to the passing of the Insurance Act, and to the improvements effected in the medical departments of the Royal Navy and the Army.

But the difficulty is of too long standing to be explained by those three factors, though it is they, doubtless, that have rendered it acute; otherwise it might be left to right itself on the principle of supply and demand. Nor, while refraining from any expression of opinion as to the merits or demerits of the suggestion that public asylums (which are at present managed by local authorities) should all be linked up to form one common service, do I believe that the adoption of that policy would of necessity render asylum work more popular as a career for medical men.

The crux of the situation lies in the fact that with the gradual increase in the number of medical appointments in the specialty, consequent upon the steady growth in the number of public asylums, the proportion, which the number of posts justly regarded as "plums"—as offering an assured, independent, and satisfactorily remunerated position—bears to the number of subordinate and hitherto far from assured positions, has unfortunately become less and less. Time was when most public asylums were small institutions, medically staffed by a superintendent and one assistant: the latter's status was comparable to that of a house physician; quite equitably only bachelor's quarters were provided for him; he was looked upon as a bird of passage and as such regarded himself. Additions have, however, been made so persistently to asylums that now, out of the 97 existing county and borough asylums in England and Wales—providing between them more than 300 medical posts—no less than 40 contain over 1000 patients, and of these in about 14 the number is more than 2000, while only 16 contain less than 500 patients. Manifestly, with such a great augmentation in the size of asylums, the number of medical officers who, for the safety of the institution, must be regarded as permanent officials has largely increased, but in the meanwhile custom has—I venture to suggest, needlessly and unwisely—decreed that the position of those officials should remain much as it was when asylums were small units; so that, while in former days 50 per cent. of asylum medical appointments were coveted and assured positions, the same can now be said of scarcely 30 per cent. In other words, the junior's aphorism that "the assistant medical officer of to-day is the superintendent of to-morrow" is lamentably untrue. Were it always a fact, the present shortage in applicants would never have arisen; but to express the truth we must paraphrase and say rather that the "superintendent of to-day is the assistant medical officer of yesterday"; and, indeed, the briefest consideration of the expectation of life suffices to demonstrate that unless men are seldom appointed to the position of superintendent until they are well past the prime of life—a policy not to be recommended—only a limited number of assistants can count on attaining to that position.

(*ii.*) *To overcome the unpopularity.*—But if I have hitherto painted to you the darker side of asylum service, I am entitled to show you its brighter aspect; and it has one. In the first place, the disabilities of the service, some of which I have indicated, are recognised and admitted as evils. That is a great step, and it is gratifying to add that, not only have several local authorities substantially mitigated them by granting (*a*) *increases in salaries and the provision of separate houses for assistant medical officers*, lending hope to our being within measurable distance of seeing the principle accepted that no resident male official in our asylums, whose services it is desired in the interests of the institution to retain over a series of years, shall be debarred either from marriage or from other social advantages, including a reasonable independence of position; but also a healthy spirit has arisen calling for evidence of greater scientific training in the specialty on the part of those practising in it, as witnessed by (β) *The institution of diplomas in psychiatry* by the Universities of Durham, Edinburgh, Manchester, Leeds, and Cambridge (enumerated in the order in which they adopted this step); besides which mention may be made of the fact that in London and at the four Scottish Universities psychiatry is now a branch in which the degree of Doctor in Medicine may be obtained. The institution of these diplomas is a recognition of a movement of probably far-reaching importance, and it is not an exaggeration to say that it marks an epoch in the progress of psychiatry. That they will become registrable by the General Medical Council is a further step that I venture to hope will not be long delayed. Some of you are conversant with the beneficial effects upon the sanitary service of the country which followed upon the enactment of the compulsory holding of diplomas in public health; and many of us believe that similar benefits would flow from a like policy in the case of the diplomas in psychiatry; not, of course, that it is in the mere possession of diplomas that their potency resides, but rather in the knowledge and systematic study of which they are the hall mark. The existence of these diplomas has already emphasised the pressing need for (γ) *the establishment of psychiatric clinics.* The fact that one, to which I shall have occasion again to refer, will shortly be at work in the metropolis under the ægis of the London County Council is a matter for earnest congratulation; and not less satisfactory is the recent erection at Cambridge of laboratories for the prosecution of experimental psychology. May the time rapidly come when these institutions will no longer stand out as oases, when none of our medical schools but is in possession of both of them, and when none of our towns of any magnitude is lacking the former. The evolution of these clinics is one of the directions towards which it is of paramount importance to secure not only the sympathy but also the active intervention of general hospitals. Such clinics would enable the study of the various branches of psychiatry and psychology to be coördinated into a well articulated scheme, embracing ante- as well as post-graduate study; and would be the means of securing, as is so much to be desired, (δ) *a more satisfactory position for psychiatry in the medical curriculum.* Few if any teachers in psychiatry can be satisfied with the position that their subject occupies in the medical curriculum. The compulsory attendance on four-fifths of 12 systematic lectures in the school and 12 clinical demonstrations at a recognised institution for the insane is what is usually demanded of the medical student. The subject enjoys the distinction—some will say an enviable one, and there is much to be said for their contention—of being the only compulsory one in which (as respects by far the majority of qualifying examinations) the student is not examined. Far be it from me to advocate yet another addition to the student's trials by examination, nor have I sufficient experience as an examiner to enter into the controversy of written examinations *versus* credit for work done in the class as ultimate tests of the candidate's fitness to practise his profession—*in medio tutissimus ibis* will, I suspect, be the solution. But it does seem to me anomalous that of all courses which the student is called on to attend he is exempt from any proof of competent knowledge in the one with which the liberty of the subject is so intimately involved. Either the certificates of attendance on the course (which is now compulsory) should include satisfactory evidence of knowledge attained and work done, as well as mere attendances, or the final examination in medicine, both written and clinical, should always include a test as to the candidate's knowledge of mental diseases.

Adverting for a moment to the nature of this course—of all subjects, the teaching of mental diseases is one which lends itself rather to clinical methods than to systematic lectures; and freedom should be given to the teacher to proportion the time between the methods according to circumstances. But that privilege would go only a small way towards adequate reform; for as matters now and would still stand, the clinical demonstrations necessarily all take place in institutions removed from the medical school—commonly at a considerable distance, though sometimes, it is true, comparatively near at hand. In either event the student sees only certified cases of insanity, and for the most part cases in which the stage of the malady is considerably advanced. He learns something of the classification of mental diseases, of the diagnosis of the forms as they are presented to him in the asylum and of their treatment, and is instructed in the mode of filling in certificates of mental unsoundness. This is all to the good, and I should strongly deprecate the abandonment of asylum clinical demonstrations. But what he almost wholly misses is an opportunity of seeing those borderland and incipient cases, with the difficult technique of whose examination he should have, if not a familiarity, at least an acquaintance—that is, if he is to be competent to render that spiritual aid which, without encroaching on the province of the priest, is more and more expected of medical men; for they it is, as said the Dean of St. Paul's at the last International Medical Congress, who now hear the confessions of anxious and conscience-stricken patients. If it is pardonable to glance at the commercial aspect of the question, I have no hesitation in saying that on ability or inability to deal with these cases will often depend the retention of a family in the doctor's general practice. Moreover, under existing arrangements, the student's access to cases of mental disorder is usually limited to a weekly visit, whereas it cannot be denied that of all branches of clinical medicine the student of mental disease should have, under proper supervision, free and daily access to a mental ward and mental out-patient department.

For the realisation of these aspirations I would again repeat that we must enlist the interest and energetic coöperation of general hospitals, and in this direction I need hardly say that, to my mind, the establishment at Middlesex Hospital of a special department for nervous diseases was a very bright omen, even limited as it at present is to out-patients, though the addition of beds to it would, I am sure, materially add to its sphere of usefulness.

(iii.)—Advice to entrants into asylum service.—Before quitting the subject of the present unpopularity of asylum service I should like to express, firstly, my conviction that, with the recognition that has already taken place of some of the existing drawbacks, the neck of the difficulty has been broken; and, secondly, and speaking with a full sense of responsibility, my hope that, despite any warnings he may have heard, no student of this school who is willing to work hard and apply himself seriously to the study of psychiatry as a branch in which to specialise will be deterred from following his bent. If I may be permitted to offer

a word of counsel I would, however, advise him to be cautious in his method of procedure, and especially not to let considerations of £ *s. d.*—important though they may be—be the only nexus between himself and his choice of place. After serving the usual term as house physician or surgeon he would be well advised to endeavour to attach himself to an asylum affiliated to a medical school, whence, after an adequate period of study and training and after making sure he has attended all the courses obligatory for one of the diplomas in psychiatry, he can migrate to other institutions which, though perhaps less favourably situated, offer advantages in salary and promotion. No such aspirant for reputation in psychiatry need, I am convinced, fear being side-tracked and, even if he does not ultimately reach the position of superintendent—and not every military officer becomes a general nor every naval officer an admiral or even a captain—he will be able to present claims to an honourable and assured position which cannot be disregarded.

2. *Psychiatry's claims overlooked by philanthropists.*—Though the pecuniary recompense paid to the actual toilers after knowledge is too often slender and in the nature of a pittance the progress of science, nevertheless, owes much to the liberality of wealthy benefactors. To criticise the direction of their benevolence would be a sorry and ungrateful act. Rather, did time permit, would I enumerate all the endowments that have been made in recent years to the various departments of medical research. Such a catalogue, while redounding to the credit of the donors, would serve my purpose by emphasising a patent hiatus that most assuredly deserves to be filled in. For at any rate during the 20 years during which I have been connected with the specialty, with one exception, conspicuous by its solitariness as well as by its munificence and far-sighted policy—I refer to the Maudsley Hospital in course of erection—I cannot call to mind any donations or legacies which have had for their object the endowment of psychiatric research in this country.

This is the second count in which, I suggest, psychiatry is indeed and undeservedly the Cinderella of medicine. By no manner of means can this cold shoulder which she receives be explained by any lack of problems of interest; indeed, nothing would be more congenial than to be called upon to give an address entitled, "Things we should Like to Know in Psychiatry," to an audience of millionaires anxious for some guidance in the distribution of a moiety of their wealth; nor would it be difficult to supplement the list of problems with chapter and verse of the immediate benefits that might be expected to flow from their answers. It is to be doubted, however, if such a campaign, even though entrusted to a master in oratory, would be as moving as knowledge gathered by personal observation—who sees with the eye, believes with the heart, and there is no little sagacity in the dictum that "you cannot convert a man unless you persuade him he is obeying the dictates of his own heart."

For that and other reasons it is a misfortune that so slender a proportion of ratepayers, particularly of their *intelligenzia*, ever visit and make themselves personally acquainted with the 97 asylums which their money provides and in which are maintained some 105,000 patients. Many of these institutions are situated in country districts away from the throb of active life, and, except for the visits they receive from official visitors and from the friends of a proportion (often too small) of the patients, they are left severely alone—verily, out of sight out of mind. And what would the intelligent ratepayer learn? Speaking generally, he would be amply satisfied with all he saw, and that his money was being economically and humanely spent. Here and there he would be impressed by centres of serious effort to unravel, with an energy deserving of the highest praise, the perplexities which surround the cause and treatment of mental affections. His interest aroused, as it inevitably would be, particularly if it were backed by some knowledge of the intensive methods of research and their cost in other branches of medical science, he would begin to inquire into what relation the sums spent on psychiatric research bear to the cost of the patient's maintenance. He would probably be a little staggered to learn that the latter (not even including the cost of repairs to fabric and other capital charges) is well over two and three-quarter million pounds a year; but with what derision and almost incredulity would he hear that, at a liberal estimate, it would be hard to show that even so insignificant a fraction as 0·2 per cent. of this sum is spent in organised scientific research?

It is, however, a fact of much significance and one very pleasing to chronicle, that quite lately the Government has set apart, to be distributed by the Board of Control, the sum of £1500 to be spent in each year in the encouragement of the investigation of mental defect in the broadest sense of that expression—thereby setting the imprimatur of the State upon the claims of psychiatry. This recognition and the advent of the Maudsley Hospital are bright streaks which, it is to be hoped, herald the dawn of a brighter day for Medicine's Cinderella.

B.—CAUSE OF PRESENT POSITION OF PSYCHIATRY.

The essential cause of the present position of psychiatry has its roots in the past and is undoubtedly the divorce that has been decreed between it and other departments of medicine. This is due to the prevailing custom, not only of treating the majority of cases of mental disorder in institutions devoted solely to that end, but also of refusing to admit such cases to general hospitals. This custom is not new, for we have records of the existence, as far back as the year 1400, for example, of a small establishment at Charing Cross and another at Barking for at least the segregating, if not the treatment, of a few insane persons; and it probably owes its origin to the failure to realise that many morbid mental symptoms are due to the same pathological conditions as are the symptoms of other systemic diseases. That "a precedent embalms a principle" has surely been exemplified here, and nowhere, I should imagine, with more disastrous results; more particularly has the custom retarded progress in the case of those areas which have the good fortune to possess within them a university—with which intimate coördination of research workers, in lieu of the mischievous and wasteful system of segregation, could have been sought.

It cannot, I admit, be gainsaid that at least superficially there are serious differences between cases of mental disorder and cases ordinarily regarded as eligible for admission to the wards of a general hospital. Though each of these differences presents difficulties of its own, I cannot agree either that any one of them ought to be allowed to be a ban on the patient's entrance into a general hospital, or even that all of them in conjunction constitute any insuperable obstacle. On the contrary, I urge that the time has come when they should cease to be permitted to encompass a gulf, almost indeed as "profound as that Serbonian bog," which has so long separated the treatment of mental from other forms of disorder.

C.—WHEREIN CAN GENERAL HOSPITALS BENEFIT PSYCHIATRY?

General hospitals can benefit psychiatry by bridging over the gulf to which I have just alluded; and this, I submit, could be effected by the establishment in general hospitals of mental wards with corresponding out-patient departments. In the case of hospitals in association with medical schools they would naturally assume the form of full psychiatric clinics.

Specialism in General Hospitals.

Specialism in general hospitals has most assuredly come to stay, and though some deprecate its triumph they may at least take comfort from the fact that in its birth it was the twin of the inevitable complexity born of the progress made by medical science. The tendency to build special and independent hospitals for this and that disorder seems, and I think happily, to be on the wane. This has been effected by the response made by general hospitals to the demands of specialism; and now many a large hospital strives to have under its own roof departments for all the specialties that have arisen—wards for diseases of the eye, of the nose and throat, of the ear, of the skin, for nervous diseases, for genito-urinary diseases, for cancer, children's wards, maternity wards, and a dental department. But the gamut is incomplete, for if there is one department that, willy-nilly, has been dubbed a specialty it is psychiatry. Yet in our own country, so far as I am aware, not a single general hospital can boast a psychiatric clinic in the full sense of the term.

The debt that the public owes to general hospitals and to their medical staffs, who gratuitously and so lavishly give their time, would indeed be hard to compute. It sits lightly on the shoulders of most of those who use those institutions because they are ignorant of the work that goes on within their walls; they regard the cure of their malady as an empirical procedure. It is only the more enlightened that have any glimmering of the fact that each case is a new problem; that its history, course, and result are laboriously recorded, and are subsequently not pigeon-holed as dust collectors, but classified to form a living library for reference in future cases.

Consciousness of this debt and desire not to be presumptuous make one hesitate in any way to criticise; but, if I may be forgiven using a somewhat hackneyed quotation, I will take leave to say to general hospitals, and to throw into my question a spice of reproach, "Canst *thou* not minister to a mind diseased?" I am convinced they can if they will.

The Pyschiatric Clinic.

Mental wards in general hospitals are not an entirely modern conception. There may have been other examples; but it is certain that in the year 1724, when Guy's Hospital was established, its founder stipulated that insane persons discharged from certain other general hospitals were to be received; and in 1797 a special "house" in connexion with the hospital was built which continued to receive insane patients down to the year 1859. That it was not a success, and that, down to its abolition, the then Commissioners in Lunacy pressed for its removal into the country, are facts which have sometimes been put forward as evidence against the soundness of the principle. But the further fact should be noted that it was expressly stated that the 20 cases, which this mental ward was to accommodate, were to be all certified as incurable; and it is indisputable, from the ward's annual returns, that it was not uncommon for a year to pass without any admissions, that discharges were few, and that apparently none were recorded as having recovered—surely the negation and antithesis of our conception of a psychiatric clinic.

The ideal Psychiatric Clinic has probably yet to be developed, and each new one should mark in its design progress in method of treatment. As regards this country it has as its prototype the admirable admission hospital which now exists as a detached unit in several of the county asylums. While brains are more important than bricks, no little cunning is nevertheless requisite in the actual design of the building; for, besides adequate out-patient rooms, it internally has to provide accommodation for every type of mental case, so arranged that no patient need be disturbed, alarmed, or suffer any shock by the behaviour of a fellow patient; and withal, as much of the treatment in bed as possible should be capable of being in the open air. There must, moreover, be means of classifying the patients according to the stages they attain towards convalescence. Opportunity should be provided on a liberal scale of employing every known special form of treatment which experience teaches promotes mental recovery. Properly equipped clinical rooms for examination of patients on admission and afterwards are essential. Rooms adaptable for work in practical psychology should be included, and a certain amount of laboratory space would also be needful; but as to the latter, the situation of the clinic, within the curtilage of a general hospital, would enable advantage to be taken of existing laboratories.

That such an institute could prove a failure is as inconceivable as inestimable would be its benefits.

Out-patient departments.—As ancillary adjuncts to the wards, mental out-patient departments would, of course, be a necessity, and of their power to stave off many a threatened mental breakdown I have not the shadow of a doubt. In the general hospitals attached to a few medical schools (among which is Middlesex Hospital) and in at least one public asylum they already exist; but I can see no reason why they should not be established in connexion with every general hospital in the country, nor why the expert knowledge of the medical officers of institutions for the insane should not be freely available and made use of—that they would be readily given there need, I am sure, be no misgiving. Such out-patient departments, if they are to fulfil all the functions I have in view, should be attached to the general hospitals and not to the asylums.

Mitigating the stigma of insanity.—Owing to much misunderstanding, both as to the liability to relapse and on the question of the influence of heredity, a most unfortunate stigma attaches to a person known to have had a mental breakdown, especially if the case has been placed under legal certificates. Whilst wholly undeserved in a large proportion of cases, how real it is in the view of the public and how powerfully it operates as a deterrent to prompt and efficacious treatment, only those of us who see these cases fully appreciate. No amount of preaching will stifle this sentiment; but the institution in general hospitals of the psychiatric unit, access to which could be obtained through the ordinary portals of the hospital, would be the most powerful factor possible in nullifying its evil influence.

Teaching facilities.—Upon the advantage that would accrue to the students and to post-graduate study and research I have already dwelt. Our students, by daily observation, would be enabled to familiarise themselves with cases not crystallised but in plastic and incipient stages—the very forms that they will meet in general practice.

Opportunity would also be given to the general nursing staff in turn of becoming acquainted with mental nursing—to the advantage of both branches of nursing.

Legal restrictions have sometimes been advanced as reasons against the possibility of use being made of general hospitals for that purpose. Speaking quite unofficially (as I am throughout this address), I would merely say that I believe that the legal difficulties have been exaggerated, and I do not think they would operate to prevent the establishment of psychiatric clinics. It is true that to utilise the latter to their full extent some amendments in the present law would be needed, and there is good reason to hope that ere very long these will be obtained, and that among other facilities they may render possible the coöperation between asylum local authorities and the governing bodies of general hospitals.

CONCLUDING REMARKS.

My task is done. If this address has consisted only of commonplaces, each useless perhaps by itself, my object has been to bring them to a focus, to place somewhat more in the limelight the claims of psychiatry, and to put forward a plea for a wider sympathy with its needs. If peradventure one be found here whose attention has been engaged by any of my remarks, I beg him not to be satisfied with taking for granted what I have said, but to look into the question for himself; I have confidence that his interest, once aroused, will not flag, but will bear fruit. As to the part in the problem I hope some day to see general hospitals play, if not presumptuous, I would venture earnestly to ask the authorities of this hospital to consider the feasibility of adding to their units a psychiatric clinic. Has it not been the steadfast determination of the Middlesex Hospital to provide the fullest opportunities for teaching, study, and research in every branch of medical science, not only as respects the preliminary and intermediate subjects, but also on its clinical side? If I have dared to suggest that a gap exists in the latter, it is one that, as far as I am aware, is common to all other general hospitals in this country, and if the Middlesex Hospital resolved to lead the way in filling it in or bridging it over its action would surely be no departure from its considered policy, but rather the fulfilment of its highest and best traditions.

INCONTINENCE OF URINE IN WOMEN.

BY DAVID NEWMAN, M.D. GLASG., F.R.F.P.S. GLASG.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY.

As observed clinically, cases of incontinence of urine in women may be divided etiologically into four classes: those in which the incontinence is secondary to some vesical lesion, such as cystitis, calculus, or tumour; those in which it is due to a bacillus coli infection of the bladder associated with localised hyperæmia around the neck and in the lower part of the trigone; those in which there has been some injury to the neck of the bladder or to the urethra; and those where no history of traumatism can be discovered and no lesion can be found on physical examination. Incontinence arising in the course of vesical disease or from bacillus coli infection will not be included in our present inquiry; attention will be limited to conditions involving injury to the neck of the bladder and urethra, and to those cases in which local examination reveals nothing to the eye.

Some kind of injury, obstetrical or surgical, is by far the most common cause of incontinence in women. In those who have borne children, especially multiparæ, the neck of the bladder or the urethra is liable to suffer injury to the muscular tissues, the structures which control the discharge of urine. During parturition the sphincter of the bladder is exposed to injury and the structures of the urethra may be overstretched; or by the introduction of large surgical instruments, and especially by that most unsurgical procedure digital examination of the bladder, the urethra and neck of the bladder may be so seriously injured that control of the escape of urine is lost. Doubtless the female urethra may be dilated either with the finger, with forceps, or with a full-sized urethral speculum, while the patient is under an anæsthetic, without producing much harm. Even after considerable dilatation rapid recovery may occur, but there are not a few cases where undue dilatation of the urethra and neck of the bladder leads to what has been regarded as insuperable incontinence of urine and never-ceasing annoyance to the patient. It is the purpose of this article to show how these cases can be improved or cured by operation.

On standing or on sudden exertion urine escapes. This is very distressing to the patient, and prevents her from associating with her friends or going about with any freedom. The escape, whether it be continuous or intermittent, is always beyond control, and necessitates wearing of gauze pads, which require to be perpetually changed if irritation from the discharge is to be avoided. Even with the most careful precautions considerable suffering may be induced by excoriation of the external genitals; the odour becomes offensive, the knowledge of the condition of matters prevents the woman from going into society, and her life becomes in every way miserable.

In these cases the mucous membrane and muscular walls of the bladder are usually healthy; the structures of the neck alone have been injured. There is no serious degeneration of the tissues, the nerve supply is good and efficient, and the condition may be cured by operation.[1]

---

[1] In an article illustrating certain urinary conditions in women associated with frequent or painful micturition (Glasgow Medical Journal, May, 1913) the writer mentioned an operation he employed for such cases, but did not describe it in detail. The object was to unite the fibres of the sphincter at the neck of the bladder and narrow the urethral canal throughout its course. The object of the operation about to be described will be seen to be different.

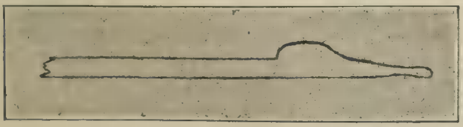
In the second class of cases, those in which no disease or traumatism can be discovered, the patient seems to be reduced to the state of the infant who passes urine unawares, and as if the control of the will was in abeyance. The will has no power to control. Much the same condition is seen in nocturnal incontinence in young girls; in these, however, the incontinence is during sleep or just at the time of awaking.

The incontinence may begin in various ways. Generally the development of the ailment is slow. A small quantity of urine escapes almost unknown to the patient except for the wetting of the garments. Gradually the accident becomes more frequent, and larger quantities of urine escape from time to time. No importance or significance is attached to the condition, it may be many weeks or months, but as matters grow steadily worse the patient and her friends become distressed and alarmed as to the future, especially as medicinal treatment produces little or no improvement. Ultimately complete incontinence becomes established with all its evil effects, both mental and physical. It is one of the most distressing and intolerable of the minor maladies to which females are subject, and the more so as seldom a cure by operation is attempted. The case is simply allowed to drift because a belief has been accepted by many surgeons that little or nothing can be done.

It is outside of the scope of this article to give an account of or to criticise the many methods which have been adopted from time to time to cure incontinence in women, the object being only to describe an operation which the writer has found to be successful in a considerable number of cases during the last 15 years. He first used it in 1899. In almost all the cases the incontinence was of old standing, so that the muscular elements of the sphincter were wasted and incompetent. Consequently the object of the operation was not to restore the sphincter action, an end no doubt desirable, though unfortunately not attainable, but rather to offer simply a mechanical obstruction to the too easy escape of urine. The operation was therefore directed to diminishing the lumen of the first three-quarters of an inch of the urethra, and at the same time constructing a firm mound of mucous membrane on the floor of the bladder just inside the neck—to imitate, as it were, the obstruction seen in enlargement of the middle lobe of the prostate in the male.

The patient may be placed either in the lithotomy or in the elbow-knee position. In the following description we will adopt the former; the pelvis is well elevated, the knees widely apart, and the posterior wall of the vagina fully depressed, so as to expose the anterior wall fully to view. The bladder is distended with 12 ounces of boric solution. A straight steel bougie, No. 14, with a knob of the size and shape of a horse-bean half an inch from its point (Fig. 1), is introduced into the bladder, at first fully and then partly withdrawn, so that the knob comes down to and locates the neck, and by elevating the handle of the bougie the knob is made to throw out the posterior wall of the bladder immediately above the sphincter, and so project it backwards and downwards. Three sutures, one anterior and two lateral, are now passed through the lips of the os, and the uterus is dragged downwards so as to give a clear view of the anterior wall of the vagina.

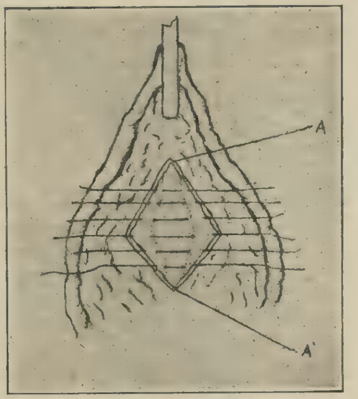
FIG. 1.



Bougie for introduction into bladder.

A median vertical incision is now made from the uppermost point of the knob of the bougie downwards over the knob and along the middle of the stem for a distance of one and a half to two inches. With blunt-pointed scissors cutting on the flat the mucous membrane and muscular coat of the vagina are carefully separated on both sides of the median incision. The dissection should be made right down to the submucous tissue of the bladder and urethra, but great care must be taken not to expose the vesical mucous membrane itself. The vaginal mucous membrane is removed over a lozenge-shaped area (Fig. 2, A A′), the centre of which corresponds with the position of the most prominent part of the knob of the bougie; the upper angle is just over the point of the instrument. The lower angle corresponds with the stem, while the two other angles point outwards, one on either side. Incisions are now made to join the apices, and a lozenge-shaped portion of vaginal mucous membrane is removed, exposing a corresponding area of raw surface, the floor of which covers the neck of the bladder and the first half inch of the urethra.

FIG. 2.

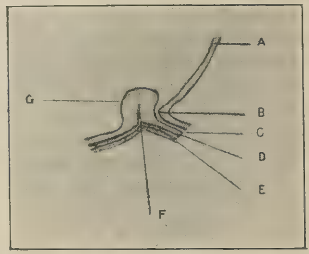


To show method of passing sutures.

The vesico-vaginal septum having had the vaginal stratum removed over the area mentioned, the next step of the operation consists in building up a dam to prevent the too easy escape of urine. The successful construction of this mechanical obstruction depends upon heaping up a bank of mucous membrane on the vesical side of the septum and supporting it by tightening the structures behind—those on the vaginal side. (Fig. 3.) Make the first redundant, the second scant. The raw surface exposed is about one and a half inches in length from above downwards, and from side to side three-quarters of an inch. The broadest part of the lozenge is over the neck of the bladder.

The next stage of the operation is the suturing. The bougie is still in position. The sutures are chromic catgut and are introduced as follows. (Fig. 2.) A deep row is planted as shown in the illustration. On the left lip of the wound the needle is passed from left to right; it enters immediately under the vaginal mucous membrane to come out one-eighth of an inch to the left side of the centre line of the bougie; it is then carried over the rawed surface to one-eighth of an inch beyond the right side of the bougie, where it penetrates the tissue, to be brought out on the right lip of the wound. Six sutures are passed in this way as shown in Fig. 2. The bougie is now withdrawn, and the sutures are tied, cut, and buried. A second row of fine gut sutures is applied to unite the margins of the wound in the vaginal mucous membrane, and the operation is completed. No special after treatment is required, except that it is well to retain a small-sized rubber catheter for the first six or eight days, and to cleanse gently the parts twice daily.

FIG. 3.



A, Bladder wall. B, Neck of bladder. C, Urethra. D, Posterior wall of urethra. E, Vaginal wall. F, Cut surfaces sutured. G, Mound of mucous membrane.

The most common causes of simple incontinence of urine in women—that is to say, loss of control unassociated with disease of the bladder or the urethra—are injury received during parturition and over-distension of the urethra and neck of the bladder by instruments. As a result of these injuries a secondary cystitis or urethritis may be set up which aggravates the suffering considerably. There are other cases where no history of traumatism can be discovered. The former are more amenable to surgical treatment than the latter, but even these may be much improved by the operation suggested above.

Glasgow.

MULTIPLE ROUND-CELLED SARCOMA ORIGINATING IN THE NARES.

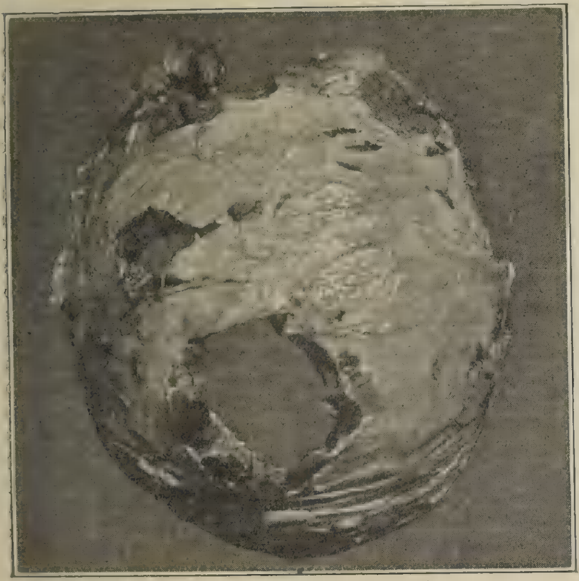
BY C. N. SLANEY, M.R.C.S. ENG., L.R.C.P. LOND.,
DEPUTY MEDICAL OFFICER H.M. PRISON, PARKHURST.

A MAN, aged 43 years, was brought under notice in February, 1912, complaining of being unable to breathe properly through the nose on account of it being stopped up more or less in both nostrils. This condition gave rise to continual sore-throat, cough, and general discomfort, in consequence of the patient having to go about with his mouth open. He stated that he had been told by a medical man whom he had consulted in the matter that he suffered from a polypus in the nose, and also that he had received treatment for this condition during the year 1909, when the growth was removed, and that it had again recurred. He was a heavy, thick-set man, 5 ft. 7 in. in height, and weighing 168 lb.; of pale complexion, but apparently in robust health; a woolcomber by trade. He expressed the wish that the polypus should again be removed in order to relieve him from his discomfort. A history of syphilis and gonorrhœa was elicited; but apart from these two diseases, which had apparently never worried him very much, he had enjoyed excellent health.

On examination there was found a fleshy, movable, pedunculated growth about the size of a large walnut, reddish-purple in colour, occupying the nasopharynx and extending, as far as could be ascertained, from the upper part of the posterior nares downwards behind the soft palate. It was situated more to the right side than the left, and could be pushed by the finger upwards and forwards towards the right nostril, being moulded to adapt itself to its surroundings, and ending in a blunt point at its posterior free end. Viewed through the right nostril, which it tended to obliterate, it presented a soft, œdematous, glistening appearance. There were in addition one or two small nasal polypi of the ordinary pale gelatinous type present in both nostrils, and a thin, clear, inoffensive watery discharge, very slight in amount, was noted. On account of the general œdematous condition of the mucosa covering the surrounding tissues the exact origin of the fleshy mass, although it appeared to occupy the right side of the nose for the most part, could not be accurately determined. In response to his request that something should be done to give him relief as much of the growth as could be seen and felt was removed by the wire snare under local anæsthesia. The tumour was very friable and not easy to manipulate; comparatively little hæmorrhage occurred during the operation. As a result of this he was again able to breathe through the nose, the throat and chest troubles vanished, and he could sleep in comfort.

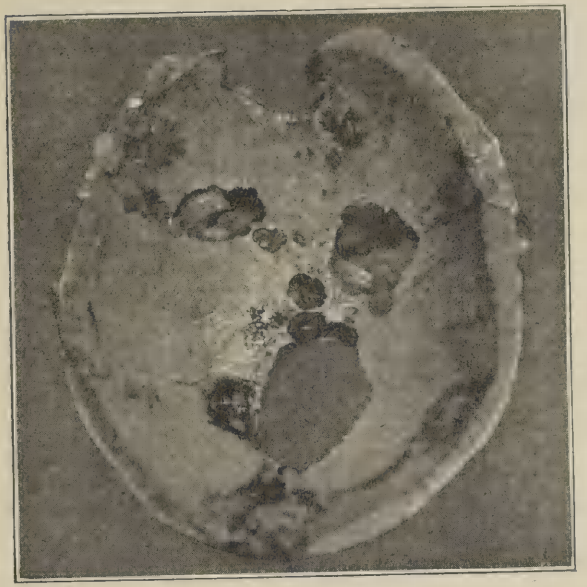
The patient again presented himself in January, 1913, having apparently enjoyed good health in the interval, complaining of pains in both knees and in the left shoulder, which he attributed to rheumatism. There was œdema of both feet, and the right side of the nose was found to be obstructed by new growth. The urine was acid in reaction, clear, and normal in colour, with a specific gravity of 1014, and it contained a minute trace of albumin. Under general treatment he improved in health and was able to get about. There was little or no alteration in his general appearance to be made out, but towards the end of March of the same year a soft fluctuating swelling, gradually increasing in size, made its appearance under the scalp in the middle line over the upper part of the frontal bone. This was quite painless and so insidious in character that for a considerable time he appeared unconscious of its presence. A few weeks later there followed another swelling, similar in character to that over the frontal bone, in the neighbourhood of the inner canthus of the right eye. Albumin in the urine, at first very slight in amount, gradually increased in quantity, the addition of a few drops of hydrochloric acid causing a white precipitate. Although he was ordered to bed, it was found expedient, as he was heavy and difficult to nurse, to humour him as much as possible, and he was allowed to get up at such times throughout the day as he deemed compulsory. On August 1st, 1913, he suddenly fell down whilst standing by the side of the bed. In all probability this fall was occasioned by the breaking of one or more of the long bones of the leg; but whether this was so or not it was found on examination that he had sustained a fracture of the right femur apparently just above the condyles, and also of the left tibia and fibula through the lower third; of the right radius and ulna at about the middle of the shafts, and another fracture in the region of the left elbow joint. The condition of the bones at the site of injury was consistent with the presence of new growth within them. The accident did not give rise to any shock. Under suitable treatment the fractured bones tended to heal satisfactorily as far as the position of the limbs was concerned, but the union was not very firm. Other tumours, similar in character to the one which made its appearance in the frontal region, gradually appeared under the scalp, in the proximal phalanges of the fingers, and on the right instep, that at the inner margin of the right orbit, as it increased in size, causing downward and outward displacement of the eyeball, giving rise to diplopia. As time went on, towards the end of the year, he complained of severe headaches, and attacks of nose-bleeding were not uncommon. It was estimated by the nurse that on one occasion he lost 16 oz. of blood from the nose during the night. The temperature at all times was irregular, running between 96·8° F. in the morning and 101° in the evening. His appetite remained good, and if anything he increased in weight. All tumours were slowly increasing in size, and he was quite unable to breathe through the nose, as a result of which symptoms of bronchitis made their appearance. On Jan. 22nd, 1914, in spite of the cheery optimism which never deserted him, it became obvious to those in attendance that dissolution was imminent, dyspnœa was very marked, and only with great difficulty was he able to draw air into the lungs, the act of inspiration being accompanied by a low, wheezy, hollow sound. The temperature rose to 104°, with slight morning remissions, the pulse-rate was 152, and four days later he succumbed in the early hours of the morning, conscious almost to the end.

FIG. 1.



Exterior view of vault of skull.

FIG. 2.



Interior view.

The report of the post-mortem examination describes the body as being that of a fat and well-developed man. Rigor mortis was still present. Many tumours of various sizes were visible to the eye—namely, under the scalp, one a short distance in front of the bregma, 4½ inches in diameter at its base; another in the right temporal region 1⅝ inches in diameter; and another at the top of the vertex in the middle line 2¾ inches in diameter; two projecting from the inner wall of the right orbit and displacing the eyeball; another in the right nasal fossa; on the right forearm and proximal phalanges of the right index and ring fingers; over the metacarpal bone of the left index finger and proximal phalanx of the middle finger; on the right ankle below and in front of the external malleolus; and on the left ankle above and in front of the external malleolus. There were signs of old fractures in the region of the left elbow, bones of the right forearm, the right femur, and the left tibia and fibula. A large fungating growth originating in the mucoperiosteum at the base of the skull was found occupying the nasopharynx and the upper part of the buccal portion of the pharynx, extending forwards into the nasal fossa more particularly on the right side, eroding the right lacrymal bone, the nasal process of the superior maxilla, and invading the inner margin of the orbit displacing the eye downwards and outwards. The growth was reddish purple in colour, soft and mucoid in consistency, and generally ill-defined where adherent to the bone. On opening the thorax the pericardium was found to be loaded with fat and to contain about half an ounce of clear straw-coloured fluid, the heart was enlarged, the muscle valves and orifices appeared healthy, but there were signs of commencing atheromatous degeneration in the aorta. Pleuritic adhesions were present binding the lungs to the chest wall and to the diaphragm, and there was evidence of bronchitis and emphysema. When opening up the trachea it was found that its lumen was partially occluded by a soft swelling invading the anterior two-thirds of the tube, more marked on either side than in front, lying beneath the mucous membrane and extending from the lower margin of the cricoid cartilage downwards to the level of the membrane between the first and second rings of the trachea; the swelling was seen to be pale in colour, soft in consistency, and to resemble in its general characteristics the new growths already observed. Externally the larynx and trachea appeared healthy.

The abdominal viscera, with the exception of the kidneys which were enlarged and congested, were to macroscopical examination apparently healthy; the mesentery was loaded with fat. On removing the scalp the outer table of the skull was found to be eroded by new growths. (Fig. 1.) The latter were of a dark maroon colour and jelly-like in consistency; they ranged from the size of a pea to at least three inches in diameter, the skull being literally riddled; there were 16 erosions of the outer table visible, all these being of fair size. The growths had apparently originated in the cancellous tissue of the bones and extended laterally between the external and internal tables of the skull, tending to thin them, and in some cases going through the bone. Dependent on the stage and direction of the growth, the tumours could be divided into three varieties—namely: (1) those growing between the two layers of the skull; (2) those eroding the outer table and invading the scalp; and (3) those growing inwards invading and infiltrating the dura mater, though not penetrating it nor affecting the brain tissue; these latter were situated for the most part in the middle line and tended to obstruct the lumen of the superior sagittal (longitudinal) sinus. (Fig. 2.) The brain and spinal cord exhibited no departures from the normal. The cavities of the long bones in the neighbourhood of the fractures were found to be occupied by growth similar to that found in the skull bones, the compact tissue being in places very thin or entirely absent, the surrounding tissues forming a capsule for the tumours. In the case of the femur there was a tendency to so-called expansion of the bone. The shafts of the affected phalanges, excepting for a few fine spicules of bone scattered over the surface of the growth, had disappeared, leaving only the articular ends of the bones. It will be seen that the metastases, with the exception of that found in the trachea, occurred, as far as could be ascertained, only in connexion with bony tissue. Microscopical examination, made some months previous to the appearance of secondary growths, of portions of the tumour removed from the nasopharynx and nostril, although at the time not absolutely conclusive, gave rise to grave suspicions as to malignancy.

Mr. L. Stanley Dudgeon, of St. Thomas's Hospital, who very kindly undertook the microscopical examination of the tumours, reported that the growth exhibited all the characteristics of a round-celled sarcoma.

Parkhurst.

Dr. Robert P. Dawson, J.P., who is a councillor of the borough of Newcastle-on-Tyne, has been selected as the new sheriff for the ensuing year.

DONATIONS AND BEQUESTS.—The late Mr. John Murray, of Dublin, has bequeathed nearly the whole of his personal estate, valued at £19,000, to the hospitals of Dublin in equal shares.—By the will of the late Mrs. Eliza Dixon, of Clifton Down, Bristol, the Middlesex Hospital will receive £1050 for a cancer bed in the new ward, to be called the "Thomas Dixon" bed, and £1050 for a cancer bed, to be called the "Eliza Dixon" bed.—The late Rev. William Ridge Greenhill has left £200 and one-third of his residuary estate to the National Hospital for the Paralysed and Epileptic, Queen-square, of which he was chaplain.—King Edward's Hospital Fund for London will receive £500 under the will of the late Mr. James B. Sharp, of Reigate.

A CASE OF MEDIASTINAL PLEURAL EFFUSION.

BY ALEXANDER ROSE, M.D. ABERD.

EXTENSIVE pleural effusion limited to the mediastinum is a rare disease. So far as I am aware the only text-book that gives a detailed description of mediastinal pleurisy is that of Dieulafoy. The following case shows very little resemblance to those recorded by him and is possibly unique.

The patient, who died suddenly five days after I saw him for the first time, was a thin, sallow-complexioned man, 52 years of age. He gave a history of gradually increasing weakness, wasting, and dyspnœa of at least 12 months' duration. He had never been a robust man, having been for many years subject to slight attacks of bronchitis, but during the past 29 years, which were spent in one situation, his longest absence from work on account of illness amounted to only three days. One of his children was said to have died in infancy from "consumption." About six weeks before his last illness his feet had been swollen for a few days, especially in the evenings. He complained principally of dyspnœa. There was no cough or expectoration. He preferred to lie on his back with the head raised, as the breathing became troublesome if he lay on either side. The pulse was 84 and feeble; respirations short, and varying from 24 to 30 per minute; temperature normal.

On examination of the chest it was found that the measurements of the two sides were equal. The right side was dull to percussion from the base to the third rib anteriorly, and from the base to the spine of the scapula posteriorly. The dulness was most marked at the base, gradually diminishing in intensity from below upwards. The apex was resonant in comparison with the rest of the same side, but dull when compared with the left side. The outline of the dulness was unaltered by change of position. Respiratory sounds were absent at the base of the lung. At the angle of the scapula they were heard faintly, and from there upwards they increased in intensity till at the apex they were loud and bronchial in character. Vocal resonance and fremitus were absent over the lower half of the lung. The lower limit of liver dulness was two inches below the ribs in the right nipple line. The veins over the right side of the chest were slightly dilated. The whole of the left side of the chest was hyperresonant on percussion. In the upper part the resonant area reached to the right border of the sternum. The superficial cardiac dulness was absent, and the apex beat of the heart could not be felt. On auscultation the point of maximum loudness of the heart sounds was in the normal position of the apex. There were no enlarged glands and the urine contained neither sugar nor albumin.

A provisional diagnosis of tumour of the lung with pleuritic effusion was made, and an exploratory needling was recommended. The patient absolutely refused to allow this to be done, and so terrified was he at the very idea that his wife considered his death to be due to fright.

On post-mortem examination it was found that the right lung was adherent to the chest wall all round. In a cavity bounded by the diaphragm below, the mediastinal pleura internally, and the compressed lung in other directions, were 80 oz. of serous fluid which coagulated spontaneously.

The pleura covering the diaphragm and that covering what had evidently been the diaphragmatic surface of the lung were each nearly half an inch thick owing to the deposition of layers of fibrinous lymph. In the apex of the right lung there was a caseous mass of about the size of a walnut, while scattered through the lung were numerous miliary tubercles. The left lung was emphysematous and also contained miliary tubercles. The heart was very slightly, if at all, displaced.

In the article alluded to above Dieulafoy gives a description of five cases observed by himself or others. In all of these the fluid was purulent. Three were pneumonic in origin, and in two of these the abscess opened into a bronchus, one patient coughing up 3 oz. and the other 6 oz. of pus. In one tuberculous case a cavity of the size of an orange was found. It communicated with the right bronchus, and its boundaries were the vertebral column, ribs, and root of right lung. In the fifth case an encysted empyema in front of the hilum of the lung contained 10 oz. of pus. The patient was supposed to be suffering from chronic phthisis, but no tuberculous lesion was found. He also quotes Laennec as having seen circumscribed cases of pleural effusion between the inner surface of the lung and the mediastinum, the effusion being only "one or two spoonfuls" in amount.

According to Dieulafoy mediastinal pleurisy begins like an acute febrile attack with pain, fever, cough, and dyspnœa. This mode of onset along with the absence of glandular enlargement helps to distinguish it from mediastinal tumour. If the encysted fluid travels towards the lung and affects the mediastinum only to a slight extent the signs are uncertain and the diagnosis remains indefinite. If it travels towards and exerts pressure on the mediastinal contents the collection of symptoms known as the "mediastinal syndrome" is found. These symptoms are dyspnœa, stridor, and sucking in of the chest wall, dysphagia, distension of the veins of the chest, fits of coughing and suffocation, and hoarseness, dysphonia, and spasm of the glottis. They are caused by pressure on the trachea, œsophagus, azygos vein, and the pneumogastric and recurrent laryngeal nerves, and all or only some may be present. As a rule the heart is little affected.

The principal points of interest in the above case are the position and large amount of the effusion, the slight inconvenience caused to the patient during the many months it must have taken to accumulate, and the almost complete absence of pressure symptoms. The post-mortem findings suggest that the effusion was originally an encysted diaphragmatic one, and that its extension to the mediastinum occurred comparatively late. The lung, being tuberculous and fixed, would offer less resistance to the pressure of the fluid than the mediastinal contents and the comparatively healthy left lung offered.

It is difficult to see how the patient could have been benefited in any way by surgical intervention. If aspiration had been attempted it is doubtful whether the needle would have reached the fluid owing to the thickness of the intervening lung. If one had succeeded in drawing off any considerable quantity of the fluid, most probably another case would have been added to the list of sudden deaths which have occurred during the operation of paracentesis of the chest.

South Norwood, S.E.

Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON FOUR CASES OF SPLENECTOMY FOLLOWING RUPTURE.

BY ROBERT COX, M.B., B.CH. R.U.I.,
FEDERATED MALAY STATES GOVERNMENT SERVICE.

IN the June number of the *Indian Medical Gazette* appears a report of splenectomy following rupture, in which the writer lays stress on three points: 1. "The long period (34 hours) between the injury and the operation, an extraordinary length of time for a ruptured spleen to exist without a fatal result," and he explains it by the fact that the hæmorrhage was controlled by two injections of morphia gr. ¼ administered at intervals before operation. 2. Sepsis due to infection of silk owing to hurry. 3. The persistence of malaria in the blood after removal of the spleen. I venture to send you some notes on four similar cases.

CASE 1.—At 2 P.M. on May 7th, 1914, in Ipoh Hospital I examined a Pathan who had been run over by his own bullock cart at 2 A.M. on the previous day (interval 36 hours); the wheels of the cart, which was loaded, had passed over his back and left arm, fracturing his humerus. He complained of pain in the abdomen, which was tender and slightly rigid, the respirations were rapid, and the pulse-rate 144. On opening the abdomen through the left rectus I found the peritoneal cavity full of blood and the spleen torn in its long axis practically into halves, which were held together only by a small portion of capsule. A second incision was made outwards at right angles to, and at the upper end of, the first incision, and the spleen, which was three times the size of the normal, removed, after which the cavity was irrigated with saline and the abdominal wall sewn up with through-and-through silkworm gut sutures. Salines were given intracellularly during the operation and hypodermic injections of liq. strych. ♏v. and adrenalin ♏xx. Immediately after operation morphia gr. ½ was injected, a further gr. ¼ being given at 8 P.M., and repeated at 8 A.M. the next morning. On the night of operation I was unable to count his pulse, but the next morning it was 134 and in the evening 120; on the third day the pulse was 90 and on the fourth day 78. A differential blood count two months after operation showed: polymorphonuclears, 29·5 per cent.; small mononuclears, 32·5 per cent.; large mononuclears, 17 per cent.; eosinophiles, 14 per cent.; mast cells, 3 per cent.; and transitionals, 4 per cent. At this time the abdominal wall appeared perfectly sound with no tendency to hernia.

The points I would draw attention to are: (1) The long interval between the accident and the operation (36 hours), no morphia having been used; (2) the absence of sepsis; I consider the time spent on sterilisation was fully justified, all stitches being removed on the tenth day; and (3) the presence of malaria after operation. I fail to see why removal of the spleen should affect the persistency of malaria.

CASE 2.—On April 21st, 1912, at 9.30 P.M., a Chinaman, who had been injured in a mining accident 13 hours previously, was admitted to Kampar Hospital complaining of great pain in the abdomen. His pulse was 120, the abdomen was tender but not rigid, and he was unable to lie down. I performed a supra-umbilical laparotomy through the left rectus and removed a ruptured spleen weighing 2 lb.; after operation the patient was treated with intracellular salines with adrenalin and injections of strychnine. He died eight hours after operation.

CASE 3.—On July 2nd, 1912, at 2 P.M., I examined a Chinaman in Kampar Hospital who said he had been assaulted eight hours previously; he complained of great pain in the abdomen, which was tender and rigid. The pulse-rate was 140 and barely perceptible. He was unable to lie down. I did a supra-umbilical laparotomy through the left rectus; the peritoneal cavity was full of blood, and I removed the spleen, the visceral surface of which was ruptured; salines were given into the cellular tissues during and after operation. At 5 P.M. morphia, gr. ½, was injected hypodermically, and at 10 P.M. another gr. ¼. The morning after operation the pulse-rate was 140, and the respirations were very rapid and shallow; he got very much worse after drinking some brandy and his condition was considered hopeless. At 10 P.M. the same day both his respirations and his pulse were slightly improved. On the third day pneumonia of the left base set in and for a fortnight his condition was critical, but after that he made a rapid recovery. A differential blood count six weeks after operation gave: polymorphonuclears, 30 per cent.; small mononuclears, 63 per cent.; large mononuclears, 5 per cent.; and eosinophiles, 2 per cent. I saw him last on Oct. 1st, 1912, in the Supreme Court. At that time there was some weakness of the abdominal wall. He said he felt quite well, but was very much distressed that his assailant only got six months' rigorous imprisonment.

CASE 4.—On May 24th, 1914, at 10 A.M., a Chinaman was brought to Ipoh Hospital by the police. He had been beaten over the abdomen four hours previously. His pulse was 110, of fair volume and tension, there was dulness in the left flank, and the abdominal wall was rigid. I performed a laparotomy and removed a badly torn spleen, four times the size of the normal. The man died 20 hours after operation.

Ipoh, Federated Malay States.

BEE-STINGS AND ANAPHYLAXIS.

By A. T. WATERHOUSE, M.D. OXON.

AN instance of severe symptoms following the sting of a bee seems to be worth recording, since it appears to throw some light on the nature of such cases.

The patient, who lives in the country, is a healthy-looking man aged 53. He had typhoid fever very badly some 35 years ago. He is subject to attacks of faintness, especially when purged by a strong aperient. Otherwise he enjoys good health. He has kept bees for some years, and while attending to the hives has frequently been stung without sustaining any apparent injury beyond the local inflammation which is usual in such cases. Last June, while taking a swarm, he was stung by five or six bees at once, and seemed none the worse for his experience.

On August 6th the patient was stung on the hand by two bees. Almost immediately he began to feel a constriction of the throat, as if the glands under the jaw were enlarging, with intense throbbing of the head. His friends noticed that the face was flushed, the eyes congested, and the upper lip swollen. This was accompanied by numbness and tingling of both hands, and there was difficulty of breathing. He went to see Mr. R. N. Farrer, of Clayton West, who has kindly sent me some notes of the case from which this account is compiled. About half an hour after he was stung the patient lost consciousness, his breathing became stertorous, and his pulse feeble; in fact, for a few seconds he was pulseless. He recovered consciousness in from three to four minutes, but had another milder attack about ten minutes later. In 12 hours' time he was convalescent.

On Sept. 2nd while walking in the garden of St. John's College, Oxford, he was stung by a bee on the upper margin of the right ear. Remembering his former experience he left the college, and by the time he had reached the street he began to feel a constriction of the throat and difficulty in breathing. He walked across the road to the nearest chemist's shop and collapsed on the floor. When I saw him, about ten minutes later, he was semi-conscious and restless, with sighing respirations. The right side of the face was congested and slightly swollen. He was sweating, and the extremities were pale, cold, and clammy. The pulse could not be felt at the wrist and the heart sounds were very feeble. The sting had been extracted and ammonia had been applied to the ear before my arrival. He was given some sal volatile and compound tincture of cardamoms, and 5 minims of liquor strychninæ were injected under the skin of the arm. He gradually recovered full consciousness, and in about three-quarters of an hour from the time when I first saw him he was removed to his lodgings. His pulse could now be felt. His condition improved steadily, and on the following day his heart was acting normally. He had no diarrhœa and did not vomit. He was very listless for a few days, but made a good recovery.

At first sight there is nothing especially remarkable about these two occurrences, so far as the symptoms are concerned. Many other cases have been recorded of similar severe effects, and even death, following the stings of bees and wasps, but on further consideration one is struck by the resemblance between these serious effects and the typical symptoms of anaphylactic shock in animals. The suddenness of onset suggests a change which cannot be accounted for by the mere absorption of a minute quantity of irritant poison in a normal individual. The depressed heart's action, the sudden urticaria and vaso-motor phenomena, and the embarrassment of inspiration are all strongly suggestive of anaphylaxis, and when these alarming symptoms are produced in a man, who on former occasions has suffered no ill-effects from bee-stings, the extraordinary increase in his sensitiveness requires some explanation, and this is afforded by the supposition that he had been previously sensitised by the former stings, which at the time appeared to be innocuous.

Oxford.

LITERARY INTELLIGENCE.—The Encyclopædia Britannica Co., Limited, have decided to issue in a cheap and convenient form six volumes of selected articles from the Encyclopædia dealing with the population, Government, finance, industries, military and naval organisation, and other important material bearing on the war with regard to France, Germany, Austria-Hungary and Poland, Russia and the Balkans, Belgium, Switzerland, and Italy, and the wars of the nineteenth century. Among the writers may be mentioned Professor Wiriath and Mr. J. E. C. Bodley, Sir Donald M. Wallace and Prince Kropotkin, Professor W. A. Phillips and Mr. Wickham Steed, Mr. J. D. Bourchier and Mr. Mijatovich, Major-General Robinson, and Colonel Maude. Each volume separately will cost 2*s.* 6*d.* net, or 12*s.* 6*d.* net, the set of six.—Among the Cambridge University Press announcements of forthcoming works we notice, as having a collateral interest for medical men, "The Electron Theory of Matter," by Dr. O. W. Richardson, Professor of Physics at King's College, London; "The Propagation of Disturbances in Dispersive Media," by T. H. Havelock, M.A., F.R.S.; "The House-fly—Musca Domestica Linn.: its Structure, Habits, Development, Relation to Disease, and Control," by C. Gordon Hewitt, D.Sc.; "The Chemical Examination of Water, Sewage, Foods, and other Substances" (Cambridge Public Health Series), by J. E. Purvis, M.A., and T. R. Hodgson, M.A.; "Water Reptiles of the Past and Present" and "The Osteology of Some American Permian Vertebrates," by Samuel W. Williston; "The Origin of the Earth," by Thomas C. Chamberlin; "Isolation and Measurement of the Electron," by Robert A. Millikan; and "The Evolution of Sex in Plants," by J. M. Coulter.

Reviews and Notices of Books.

Auricular Flutter.

By William Thomas Ritchie, M.D. Edin., F.R.C.P. Edin., F.R.S. Edin., Physician to the Deaconess Hospital; Assistant Physician to the Royal Infirmary; Lecturer on the Practice of Medicine, School of Medicine of the Royal Colleges; Lecturer on Clinical Medicine in the University of Edinburgh. London and Edinburgh: W. Green and Son. 1914. Pp. 144. Price 10*s.* 6*d.*

The introduction of the electrocardiograph has afforded much valuable information regarding the nature and the causes of heart failure. This grave and often fatal event is recognised as being not infrequently a result of diseases of the auricles. The term auricular fibrillation is now extensively employed, and the conditions underlying its production are becoming more precisely understood; and the disorder which is designated "auricular flutter" has been more recently investigated.

The volume before us is mainly devoted to a study of this subject. In order that the nature and significance of the disorders of the auricles may be appreciated, some account is first given of certain facts concerning the anatomy and physiology of the heart and the pulsations of the jugular veins. The disturbances of the cardiac action that are due to extrasystoles and auricular fibrillation and their relation to allied disorders are also discussed. Auricular flutter is defined as a pathological action of the auricles characterised by rhythmic coördinate contractions of their musculature at a rate that is greatly accelerated and is usually between 250 and 300 per minute. A brief account is given of the present knowledge of the etiology of the condition, and then the morbid anatomy is discussed, the conclusion being arrived at that the number of post-mortem examinations is as yet too small to permit of any final conclusions regarding the condition of the heart in auricular flutter. But Dr. Ritchie is of opinion that the available evidence demonstrates that flutter may be associated with widespread acute or subacute inflammation and degenerative changes in the auricular musculature, and that these changes may involve both nodes and the bundle; also that these changes may arise in the course of an acute infective disease, but that more frequently they are due to disease of the coronary vessels or to inflammation extending into the muscle from the pericardium or from the mitral and tricuspid valves.

A chapter of 46 pages is occupied by records of 53 cases, 11 of which came under Dr. Ritchie's own observation. The electrocardiograms are of interest, and if the cases quoted from other observers form rather tedious reading they are none the less valuable as corroborative evidence. The clinical features of auricular flutter are thoroughly well described, and it is pointed out that the symptoms especially associated with this condition are not direct manifestations of the extreme acceleration of the auricles, but are due to ventricular acceleration and to secondary alterations in the arterial and venous pressures. Dr. Ritchie also maintains, being here in accordance with other observers, that the majority of cases of auricular flutter supervene during the course of chronic heart disease. The remarks on diagnosis and treatment are well worthy of attention.

We have perused this volume with much interest. It shows evidence of close observation and patient investigation. As the knowledge obtained by the electrocardiograph increases, the value of this instrument in clinical medicine will become practically established.

Geschwulstlehre für Aerzte und Studierende.

By H. Ribbert, Professor of General Pathology at Bonn University. Second edition. With 612 illustrations, many of them in colour. Bonn: F. Cohen. 1914. Pp. viii. + 710. Price 24 marks.

The publication of the second edition of Professor Ribbert's book on tumours is something of an event in the world of pathology and medicine. Its author is well known as one of the most eminent pathologists living, and the subject of tumours is one that he has made peculiarly his own. The first edition of the book came out ten years ago, so that, owing to the great progress that has been made in the study of the subject during the last decade, Professor Ribbert has found it necessary to rewrite almost the whole of the volume and to add over 170 of the admirable semi-diagrammatic illustrations that form so valuable a feature of the work. In addition, the whole subject of carcinoma has been cut out of the second edition; the reader who wishes to study cancer is referred to the author's large work on "Cancer in Man," published two years ago, to which the book at present under consideration forms a companion volume.

The work is divided into two main sections, a general part and a special part, as was the first edition. The former portion, covering 113 pages, gives a general account of tumour formation in its various aspects. Histogenesis, growth, malignancy, the tendency to recurrence and to metastasis, multiplicity, the influence of trauma, and many similar points are considered in detail. Particular attention is given to the theory of germinal exclusions, or embryonic rests, as the starting-points for new growths, with illustrative diagrams and accounts of cases. As is well known, Professor Ribbert is strongly of the opinion that tumours are often, or even habitually, due to the autonomous growth of minute cellular exclusions, or rests, fragments of tissue that have been cut off from their own particular physiological commonwealth of cells. The second section of the volume contains a special description of each of the various forms of new growth, excepting carcinoma, which is only briefly mentioned. As in the first edition, the author treats the terms "endothelioma" and "perithelioma" with great severity. He almost denies that endotheliomas exist, defining endothelium as the flattened cells of connective tissue origin that line the blood- and lymph-vessels and the lymph spaces; the so-called endotheliomas are generally epithelial tumours, adenomas or carcinomas. Peritheliomas are, or should be, he says, tumours derived from the perithelium described by Eberth as lining the perivascular lymph spaces; he concludes that the tumours now called peritheliomas should be named perivascular sarcomas. He supports his arguments on these points by numerous references to the literature of these much-discussed forms of new growth.

We need not attempt to mention the innumerable matters of interest discussed in a volume with such a title when written with real knowledge and authority. Suffice it to say that tumours of all kinds are described clearly and briefly, and that the illustrations do all that illustrations can do towards giving a simplified and lucid summary of the matters described in the text. There is an adequate index, and the volume, excellently got up and printed, is a valuable addition to the literature dealing with new growths.

It should be found in every medical library and in every pathological laboratory.

Researches into Induced Cell-reproduction in Amœba.

By JOHN WESTRAY CROPPER, M.B., M.Sc. Liverp., M.R.C.S. Eng., L.R.C.P. Lond. The John Howard McFadden Researches. Vol. IV. With illustrations. London: John Murray. 1914. Pp. 112. Price 5*s.* net.

PROCEEDING on the assumption, or what is termed "a working hypothesis," expounded in the previous volumes of this series, these researches consider "normal cell-reproduction and benign tumours as caused by certain chemical agents, called auxetics, such as tyrosin, creatin, &c.; and that cancerous tumours are caused by a mixture of auxetics with another group of substances called kinetics or augmentors, such as choline and cadaverine. Auxetics are produced in the body by cell-death as the result of injury; kinetics are decomposition products produced by the action of bacteria and other organisms." This volume does not touch on the immediate cancer problem. It deals with amœbæ and the way in which auxetics and kinetics excite reproduction in these cells.

The book is divided into four parts. In Part I. the characters of the amœba under natural and artificial conditions are considered, special methods of examination are shown, and the action of auxetics and kinetics described. The amœba employed was found growing in a sodium citrate and sodium chloride solution that had been left lying exposed to the air in the laboratory for some months. The author calls it provisionally Amœba ostrea. Chiffon was moistened and placed flat on a piece of glass. On this the amœba or amœba cysts were dropped and examined microscopically. Other methods used and the means to keep the amœba under favourable conditions of flow and concentration of fluid are described. Moist air chamber methods—examination on a jelly surface—were also used, as well as the jelly method for *in vitro* staining, and for observing the stages of nuclear division. The methods of reproduction and the process of conjugation were watched. It appears that asparagin, creatine, and tyrosin are auxetics, while choline is a kinetic. Tyrosin is said to produce multinuclear forms, while so-called "radiose" types were produced by the action of auxetics and kinetics. Part II. deals with the causes of encystment and excystation. The phenomena of "encystment" are already well known to biologists. The author contends that the "amœba is actually compelled to protect itself by the action of soluble substances in the environment, which are of the nature of poisons, and which are produced under natural conditions by those bacteria that are invariably associated with the growth of amœba." It appears that those amœbæ usually encyst first which are surrounded by a dense mass of bacteria. The bacterial products against which an amœba has to protect itself are choline and cadaverine. "Excystation" takes place in the presence either of the dead bodies of bacteria or of certain soluble products—probably of the nature of ferments—of the growth of living bacteria. These products are destroyed by boiling, but not by chloroform. Their action is increased by the presence of choline. Pepsin and normal horse serums will cause excystation. Part III. deals with the preparation of "pure mixed cultures"—i.e., the cultivation together of a single species of amœba with a pure strain of bacterium. "Cultures of amœba with a limited variety of bacteria were obtained, and these, when subjected to the action of 2 per cent. HCl for 24 hours or thorough drying for six weeks, were found to be free from living bacteria, while the cysts were still alive." A tabular arrangement of the results is given. In Part IV. a parasite of amœba is described. We have given quotations to show the views of the authors—views, however, which require further investigation.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLVIII., No. 4. July 14th, 1914. Cambridge University Press. Pp. 233–356. Price 7*s.* 6*d.*—The Formation of Urine in the Frog, by F. A. Bainbridge, J. A. Menzies, and S. H. Collins, is a continuation of a previous communication. In the authors' new experiments the view is taken that the urine is derived entirely from the glomeruli, and that as it passes down the tubules sodium chloride is absorbed, and the urine collected from the ureters is therefore hypotonic to the perfusing fluid. The amount of urine formed, however, is usually very small.—The Absorption and Dissociation of Carbon-dioxide by Human Blood, by Johanne Christiansen, C. G. Douglas, and J. S. Haldane. From the authors' observations, recorded in this article, it would appear that the giving off of CO_2 by the lungs is to a large extent consequent on the taking up of oxygen. Various experiments and calculations enable the authors to state that during rest in the venous blood reaching the lungs there is an average venous CO_2 pressure of 44·2 mm., and a rate of flow of 7·7 litres per minute in a person with a total volume of 4·7 litres.—The Influence of Distension of the Lungs on Human Respiration, by Johanne Christiansen and J. S. Haldane. Although observations on this subject have been recorded in respect of dogs and rabbits, hitherto none seem to have been recorded on man. The authors conclude from their experiments, which they state, that true apnœa, apart from the inhibitory nervous effects produced during actual distension of the lungs or actual excitation along other nerve paths connected with the respiratory centre, is a "chemical" apnœa. So far as the authors are aware there is now left no experimental evidence to support the vagus theory.—The Heart-Lung and Kidney Preparation, by F. A. Bainbridge and C. L. Evans. The authors have used the "heart-lung preparation" of Knowlton and Starling to perfuse blood through the kidneys of dogs. The kidneys are very sensitive to the lack of oxygen and probably also to the absence of the intermittent driving force of the heart, so that perfusion of the isolated kidney has not yielded results which could justly be compared with those obtained in the living animal. Hence the authors used two dogs for each experiment, one for the "heart-lung preparation" and one for the kidney or kidneys, arterial blood being perfused, so that the arterial blood pressure, blood flow, and temperature were under control and the gaseous exchanges of the kidney investigated. The kidney thus isolated and perfused secretes urine. The gaseous metabolism of the isolated kidney is increased when the urine secretion is provoked by the aid of diuretics such as sodium sulphate. The respiratory quotient is similar to that of the heart. The gaseous metabolism of the kidney is not altered by changes in the rate of blood flow through the organ.—The Ferments of the Pancreas: Part IV., Steapsin, by John Mellanby and V. J. Wooley. The authors find that the stability of steapsin (1) in alkaline solution is similar to that of trypsin; (2) in acidic solution is related to the hydrogen ion concentration of the fluid in which it is contained. Steapsin cannot exist in the presence of free trypsin. The destruction of steapsin by trypsin is absolute. Therefore, when pancreatic juice is activated by enterokinase, as trypsin develops, steapsin disappears. This fact affords an explanation for the presence of trypsinogen rather than trypsin in fresh pancreatic juice. Serum or egg albumin added to activating pancreatic juice protects steapsin from destruction owing to the presence of antitrypsin in them. The action of steapsin on fat is greatly augmented by bile and bile salts. Electrolytes, such as neutral salts, have no influence on the reaction. There is no evidence that steapsin in pancreatic juice can be separated into enzyme and coenzyme. The authors conclude (*a*) that steapsin consists essentially of protein; (*b*) that its destruction in alkaline solution is due not to auto-digestion but to its inherent instability; (*c*) that although the conditions in the small intestine which favour trypsin production are inimical to the continued existence of steapsin, yet the presence of protein in a dietary may facilitate fat digestion by virtue of the capacity of the protein to adsorb the first formed trypsin.—The Sensitiveness of the Respiratory Centre to CO_2 and the Dead Space during Hyperpnœa, by J. H. M. Campbell, C. Gordon Douglas, and F. G. Hobson. The respiratory centre is particularly sensitive to CO_2. It has been stated that a rise of about 0·3 per cent. in the alveolar CO_2 pressure is sufficient to cause the alveolar ventilation of the lungs to be increased by 100 per cent. above the resting value. The authors state that in all probability this observed value is really too high, and they set themselves to obtain some more precise quantitative relationship between the alveolar ventilation and the alveolar CO_2 pressure. The authors' experiments show that a rise of 2·5 mm. in the alveolar CO_2 pressure was sufficient to cause a rise of 10 litres in the alveolar ventilation, and a rise of 2·0 mm. in the alveolar CO_2 pressure was sufficient to cause a rise of 10 litres in the total ventilation of the lungs. During the hyperpnœa caused by air containing CO_2 the dead space is considerably increased.—The Cerebro-spinal Fluid: III., The General Effects of Increasing the Cerebro-spinal Pressure, by W. E. Dixon and W. D. Halliburton. In their previous paper[1] the authors dealt with the effects produced by moderate changes in the C.S. pressure on the arterial and venous pressures. This communication deals with the effects produced by greatly increased C.S. pressure. The experiments were made on dogs fully anæsthetised with urethane and morphine. A relatively small increase in C.S. pressure, artificially produced by a pump connected to the cranio-vertebral space, causes stimulation of the respiratory (least marked effect), vaso-motor, and cardio-inhibitory centres. When the pressure is increased to 300-400 mm. Hg, considerably above the normal arterial pressure, respiration ceases in a few seconds, but the other two centres remain active and the arterial pressure rises enormously in spite of the slow heart; a little later the cardio-inhibitory centre is paralysed, and the continued activity of the vaso-motor centre still further raises the arterial blood pressure—a protective mechanism which continues to force the blood along the compressed blood-vessels. If the high C.S. pressure is kept up paralysis of the vaso-motor centre ensues and the arterial blood pressure falls. On removal of the compression the centres recover in the reverse order, the vaso-motor centre first and the respiratory centre last. The spinal centres as tested by the occurrence of convulsions after an injection of strychnine recover their activity later still. The changes in venous pressure during cerebral compression vary in different animals, and are not always easy to interpret.—The Influence of a Vitamine-free Diet on the Carbohydrate Metabolism, by Casimir Funk and Count von Schönbrun. Pigeons kept on vitamine-free diet develop a tendency to hyperglycæmia with diminution of the glycogen of the liver. This hyperglycæmia is especially marked in the case of sugar-free diet, which is followed by an entire disappearance of liver glycogen. In three experiments made, the addition of vitamine from yeast to the latter diet produces a very marked formation of glycogen in the liver and a diminution of the sugar in the blood. Vitamine would seem to have a distinct influence on the glycogen metabolism. In the case of the fat-free diet the glycogen content of the liver is increased.—On Some Cardiac Reflexes, by F. A. Bainbridge. The experiments were made on anæsthetised dogs, the blood pressure and respiratory movements being recorded by the usual methods. The slowing effect on the heart of stimulation of the central end of one vagus by way of the other vagus is well known. In no case, however, does this central stimulation slow the heart by decreasing the accelerator tone. It would therefore appear that there is no reciprocal action between the vagus and accelerator centres. Acceleration of the heart is known to be produced in anæsthetised animals (with or without curare). This is mainly due, it appears, to decrease of vagus tone, but acceleration can also be caused by increase of accelerator tone, while some late increase is produced by the setting free of adrenalin. The effects on the circulation and respiration of stimulation of the sciatic nerve are very similar.—The Determination of Lactic Acid, by Charles G. L. Wolf. This paper will be specially interesting to the biochemists.—On the Constancy of the Systolic Output under Varying Conditions, by Joseph Markwalder and E. H. Starling. A continuation of papers already published from University College. From their new experiments the authors conclude that, taking the coronary circulation into reckoning and given a constant venous outflow, the output of the heart, within much wider limits than had been previously imagined, is independent of the arterial pressure, of temperature, and of heart rate.

ASYLUM REPORTS.

Scottish Western Asylums Research Institute (*Annual Report for the Year ending October, 1913*).—The work done during this year included an exhaustive examination of the cerebro-spinal fluid from a large series of mental cases, including chemical examination and immunisation experiments. Special work has also been done in the clinical examination of cases of adolescent insanity with a view to differentiating the various forms of this disease. A course of six lectures and demonstrations was given by the director, Dr. Ivy Mackenzie, at various asylums, and also a course of instruction in technical methods of blood and cerebro-spinal examinations to the medical officers of the associated asylums. Dr. Mackenzie proceeds to give a general review of the laboratory work during the last four years—i.e., since the opening of the institute. The results of investigations on the relation between syphilis and insanity go to show that the mental health of the community is affected by syphilis in at least five different ways: 1. General paralysis. 2. A form of mental affection that follows syphilitic disease of the brain vessels and coverings. 3. A form of mental affection in which the patient suffers from depression and excitement, although there is no direct evidence of the presence of either of the two foregoing diseases. 4. Idiocy and imbecility in congenital syphilis. 5. A condition of weak-mindedness in children and adults (not sufficient to be called imbecility) whose parents suffered from syphilis, although there may not be any bodily evidence of the disease in the patients themselves. In order to deal practically with this aspect of mental disease Dr. Mackenzie has made investigations as to the extent and significance of syphilis and the means of influencing its spread and curtailing its course. With regard to the latter the following conclusions are come to. It is a primary necessity that the public, and in particular young people, should be educated in these matters. Such education must not be confined to simple instruction in the biological facts of the disease; it must also include a comprehensive consideration of the social conditions which determine its dissemination and an appreciation of the problems of poverty and vice. Until the public is thus educated compulsory notification would be futile. There should be a general exposure of the conditions which lead to the spread of the disease and a drastic treatment of the housing question is to be recommended, not as a philanthropic project but as a business proposition, in the interests of the public health. With regard to prostitution, it is essential to realise that the position of women in the labour market is one of the many influences which help to recruit its ranks. Blaschko has pointed out that prostitution in large industrial centres varies inversely as employment in industry. A solution of the social economic problem would go a long way to palliate this social evil. The prevailing spirit of materialism is also a powerful factor in the spread of immorality. With regard to curative measures, Dr. Mackenzie considers that the medical student should receive a more systematic and thorough training in venereal disease; and that all hospitals should be open to venereal disease, without respect to its stage. Provision should be made for placing at the disposal of the profession generally the most adequate means of diagnosis and treatment. Steps should also be taken to provide that patients who are encountered in the administrative medical work—i.e., insured people—may be treated in a thorough and effective manner, as they are in the army and the navy. In the investigation of adolescent insanity an attempt was made to discover, if it were possible, to distinguish between organic and functional cases. The two principal methods of examination were those of the cerebro-spinal fluid and of the eyes. These investigations revealed the fact that some cases are transient, while others do not recover, and that among these latter there is evidence at certain stages of toxic influences, as shown by the eye conditions, and of tissue change as shown by the abnormal cerebro-spinal fluid. With regard to this latter type some cases begin with a profound somatic disturbance. This acute progressive stage is followed by dementia which ceases to progress until a recurrence of the acute condition occurs. The general impression has been that heredity is a more potent factor in the functional than in the organic cases.

---

[1] THE LANCET, July 25th, 1914, p. 237

Glasgow Royal Asylum (*Annual Report for the Year 1913*).—The total number of patients under treatment was 567, the average number resident being 451. The admissions amounted to 120, and were all of the private class. Heredity was acknowledged in 51, or nearly 50 per cent. of the cases. With regard to the probable causes, in 17 cases it was apparently alcoholic excess, in 12 syphilis, in 14 the epochal periods of life, in 16 bodily illness of some kind, not included in the above, in 5 mental stress, in 24 heredity seemed the sole cause, while in 15 no adequate reason for the breakdown could be discovered. The discharges numbered 98, of whom 52 were recovered, making a percentage of 43 on the admissions. Dr. L. R. Oswald, the physician-superintendent, remarks that the criticism may be made that the recoveries in mental disease are not permanent, but that a large number sooner or later relapse. The partial truth of this must be admitted, the reason being that on account of a want of knowledge of the true nature of the illness patients are exposed after recovery to risks of relapse to which they ought never to have been subjected. Mental disorders predispose to recurrent attacks, instead of conferring immunity on the patient, who, therefore, ought not to expose himself, after recovery, to the same causes which brought on his illness. Thus students and teachers return to their studies although brain work was the cause of their breakdown; alcoholics resume their alcoholic excess, and others expose themselves to avoidable stress with the inevitable result of a further attack. The deaths were 27 in number, a percentage of 6 on the average number resident. Dr. Oswald considers that the borderland and psycho-neurotic cases are suitable for treatment in the wards of a general hospital. Nothing would do more to dispel the belief that there is some essential difference between diseases of the brain affecting the mind, and diseases of other organs of the body, than their treatment side by side in a general hospital.

Ayr District Asylum (*Annual Report for the Year 1913*).—The total number of cases under treatment during the year was 711, the average daily number being 567·45. There were 162 admissions. Dr. G. Douglas McRae, the medical superintendent, remarks that, to judge from the statistics of the incidence of insanity and the general population during the last five years, it would appear that certifiable insanity has been on the increase among the male section of the community, while it is actually on the decrease among women. It is also notable that during the past five years the average proportion of cases with evidence of excessive alcoholic indulgence was 38 per cent. among the men admitted, and 16 per cent. among the women, while this year the former have increased to 50 per cent. and the latter have declined to 10 per cent. Hereditary predisposition was ascertained in only 24 per cent. of the cases. Dr. McRae also calls attention to the apparent increase in the prevalence of general paralysis; in 1908 it was present in 9 per cent. of the male admissions, but this year it has increased to 14 per cent., while it was responsible for no less than 25 per cent. of the total number of deaths. The number discharged was 93, with a recovery rate of 41·36 per cent. The high rate among the men—namely, 43·48 per cent.—however, is mainly due to the fact that a large proportion of the cases had been temporarily removed from the cause of their mental aberration—namely, abuse of alcohol. The deaths amounted to 48, the proportion on the average daily number resident being 8·94 per cent. Tuberculosis was the cause of death in only three cases. Dr. McRae considers that the steady and marked diminution in the tuberculosis death-rate of the district during the last five years is due to the provision of the new hospital, which was opened in 1906.

Cumberland and Westmorland Asylum (*Annual Report for the Year 1913*).—The total number of patients under treatment during the year was 1039, the average daily number resident being 866. The direct admissions amounted to 174, the ages ranging from 8 to 84 years. Hereditary predisposition was admitted in 30·5 per cent. of the cases and alcoholic excess in 9·7 per cent. In 31 per cent., owing to defective history, no cause for the attacks could be ascertained. Ninety-six patients were discharged during the year, with a recovery rate of 36·2 per cent. Although this rate is 3½ per cent. higher than the average in English county and borough asylums, it is 6·4 per cent. below the high rate of the previous year, and considerably below the average recovery rate of this asylum. The lowered rate is accounted for by the unfavourable type of the admissions last year. Dr. W. F. Farquharson, the medical superintendent, lays stress upon the importance of the early treatment of mental cases in an asylum, and calls attention to the fact that the greater the delay in placing such cases in a properly equipped mental hospital the more prolonged is the attack likely to prove and the less the chance of ultimate recovery. Dr. Farquharson finds that the open-air treatment appears to have a remarkable effect in prolonging the life of the bed-ridden cases. There were 72 deaths, making a death-rate of 8·3 per cent. on the daily average number resident. The cause was verified in every case by post-mortem examination.

Sunderland Borough Asylum (*Annual Report for the Year 1913*).—The total number of patients under treatment during the year was 483, the average number resident being 389. The admissions amounted to 90, which is the lowest number since the asylum was opened 18 years ago. Dr. J. Middlemass, the medical superintendent, states that the cause for this is by no means clear. Usually when trade is good the admissions tend to increase in number, owing largely to the increase in cases due to alcohol. Last year the conditions which usually contribute to the prevalence of alcoholism were present, but there was a decided diminution in the admissions due to this cause. There were only 19 of these, whereas in 1912 there were 27 cases in which it was either the principal or contributory factor in causing the mental attack. This is a very considerable decrease, and it is to be hoped that it will not prove merely temporary. Of the other causes producing mental disease, those associated with the critical periods of life range next in order to alcohol. There were 14 in which this appeared to be the chief cause. Mental stress was the cause in 11 cases. It is striking how often the death of a relation after a long and harassing illness is followed by an attack of depression on the part of the nurse. The cases of general paralysis were 10 in number. The number of these cases seems to be again increasing, after being at an astonishingly low figure. Three years ago only 5 were admitted, but since then there has been a steady slight rise. Epilepsy forms nearly 15 per cent. of all the cases. The discharges amounted to 52 for the year, with a recovery rate of 42 per cent. There were 42 deaths, of which 5 were from pulmonary tuberculosis. With regard to research work in mental disease, Dr. Middlemass states that there is probably not more than £4000 a year spent in the investigation of the purely scientific aspects of mental disease. Considering that there are about 120,000 patients in all the asylums in this country, this expenditure seems ridiculously inadequate. Progress commensurate with that which is being made in other branches of medical science can only be expected in mental diseases when there is a large army of workers, as there has been in these other branches. The necessary research work would probably be best carried out in connexion with existing Universities, which already possess the necessary laboratories, or where these could most easily be placed if not already available. To the support of these the Universities, the Government, and Asylum Visiting Committees might all contribute. To these laboratories the medical officers of asylums could have recourse for instruction and for direction in their own scientific investigations. Could such a scheme be actually set on foot there is every reason to hope that in no long time very material advances in the knowledge of the causes and the treatment of mental diseases would be made.

THE LANCET.

LONDON: SATURDAY, OCTOBER 17, 1914.

Coöperation Between the Civil and Military Sanitary Services.

FOR some weeks past all over the country training camps have been in process of formation for the new army that is coming into being to reinforce and, where needed, to take the place of our regular troops. The call has been well responded to, and the numbers of recruits coming forward are satisfactory. More, many more, are wanted, but there seems no reason to doubt that they will be forthcoming. The first half million men were enrolled in a very short space of time, a second force as large is collecting, and if yet another million are wanted they will be found, while it is most satisfactory to see that adversities, indicating the prolongation of the struggle, have led to more rapid joining of the colours. We trust that the rate of recruiting, however, will promptly increase, as it is most important that the new men should get into training before the cold weather definitely arrives.

The aggregation of large numbers of young adults, of an age susceptible to disease, in circumstances of urgency, when the arrangements adequate for a small body of men have immediately to be expanded so as to suffice for a number perhaps five or six times as great, produces a condition of danger to health. This is a matter of grave importance, and one where the civil and military authorities must work hand in hand to secure the most favourable conditions. The sanitary state of barracks in this country is probably on the whole satisfactory; in the buildings of modern construction there is no doubt that this is the case. In the smaller and older buildings probably matters are in a fairly good state as regards essentials. As for camps there has been so much practical use of these during late years in manœuvres and for training purposes that their sanitary requirements are well understood, and we may suppose that all necessary arrangements are now carried out as a matter of course. But at the present time the whole strength of our well-trained but small regular medical and sanitary staff is in the field, and not available for safeguarding the health of the new army that is being built up at the military centres in this country. Its place has been supplied no doubt as far as possible by civilian medical men and retired medical officers, who exercise a general control over the arrangements, and by men of the St. John Ambulance Association and Red Cross Society, who attend to details. Fair accommodation has been provided, and the needs of this army in regard to feeding, clothing, and equipment are being satisfactorily met throughout the country. Thus, for instance, we are now told that a sufficiency of blankets for present and future needs has been assured. Regular supplies have been arranged, private charity has to some extent been systematised, and there seems every reason to believe that as our new recruits join, their needs in camp will be met promptly.

The preservation of the new soldiers' health and the prevention of the development of infectious disease are matters of the greatest concern, not only in regard to the value of the fighting force, but in regard also to the health of the populations in the neighbourhood of the temporary camps that have been established. In spite of all precautions it is likely that some cases of infectious disease will occur, and under the circumstances the liability to spread is obvious. No doubt all the medical officers in charge of these camps are fully alive to this danger, and are carefully on the watch for any suspicious cases. Only those who have had to deal with similar rapid concentrations of human beings, and the multifarious arrangements that have to be made for their accommodation, feeding, clothing, instruction, and so forth, can appreciate the difficulties of the position and the risk there is of infection being introduced and disseminated in spite of all precautions. As we noted at the time, the medical officer to the Local Government Board, after consultation with the War Office, invited five or six weeks ago the medical officers of the Public Health Service, in districts where troops are likely to be stationed, to place themselves in communication with the local military medical authorities, and to offer their services. By so doing they would be of the greatest assistance, and especially in advising as to local water-supplies, as to the disposal of refuse, the carrying out of drainage and conservancy arrangements in accordance with local conditions, and the control of infectious disease (including provision of hospital accommodation and disinfection). It is to be hoped that the local health officer and the military medical officer in charge will be in close touch with each other—*dare operas mutuas*; so cordial are the relations between the civil and military branches of the profession that there is happily no doubt that such will be the case; it will be to the advantage of each, and to the benefit of the civil population and the troops in equal proportion. Typhus fever, enteric fever, and small-pox are named as the three diseases especially to be looked out for, especially the two latter. Small-pox ought to be a negligible item, and as far as the regular army is concerned it has practically ceased to exist; but owing to the lamentable neglect of vaccination in this country during the last few years there is now a considerable unprotected youthful population, and until the recruit has been satisfactorily vaccinated undoubtedly a real danger is to be apprehended on this account. The danger from enteric fever would arise not so much, probably, from insanitary conditions in a general sense as from risk of carrier cases. The War Office is arranging that every medical officer of health should be notified when a soldier convalescent from this disease enters into his district. Besides these cases of possible conveyance of infection it is to be apprehended that mild and unrecognised cases may also constitute a danger. Under the conditions of camp life such a danger is very greatly increased. No doubt the most watchful attention will be given to this matter, but in spite of every care experience has shown that, in the circumstances, spread of the disease is to be apprehended. However, when a danger is fully recognised it is almost overcome. The necessary precautions are well known.

The Local Government Board is actively co-operating with local medical officers of health in circumstances of difficulty, and we feel sure that every assistance will be given to the military medical officers in their very arduous task of training their men in sanitary methods and the prevention of disease, a duty of quite equal importance to that of the treatment of the sick and wounded in hospital or in the field. The work of the Royal Army Medical Corps comprehends the whole scheme of sanitation, and as Sir ALFRED KEOGH, who has now returned to take charge of the Army Medical Service, has well pointed out,[1] a "scheme of sanitation which omits to pay constant and unremitting attention to all the thousand minute details of the soldier's life, his food, his clothing, his housing, his work, can never hope to recover the ground so lost by the most brilliant schemes of water sterilisation or the most elaborate methods of disposal of excreta." In their onerous work the military authorities may count upon every assistance from the civil sanitary services which is requisitioned.

---

[1] "The Territorial Medical Service," by a Special Correspondent of THE LANCET, with preface by Sir Alfred H. Keogh.

MEDICAL SOCIETY OF LONDON.—The first ordinary meeting of the session was held on Oct. 12th. A vote of thanks to the retiring President, Sir David Ferrier, was proposed by Dr. F. de Havilland Hall, seconded by Mr. Willmott Evans, and carried with acclamation. Sir David Ferrier replied. Dr. Walter Broadbent proposed a vote of thanks to the other retiring officers. This was seconded by Dr. Steele Perkins and passed unanimously. Dr. R. A. Young, the retiring honorary secretary, replied. Sir David Ferrier then introduced the new President, Sir J. Bland-Sutton, and invested him with the badge of office. Having taken the chair, Sir J. Bland-Sutton delivered his opening address on Cancer of the Small Intestine, which is published in full in this issue of THE LANCET (p. 931). A vote of thanks to the President for his address was proposed by Mr. F. Swinford Edwards, seconded by Sir StClair Thomson, and carried unanimously.

Annotations.

"Ne quid nimis."

MITCHELL BANKS, A GREAT SURGEON.

THE third Mitchell Banks Memorial Lecture was delivered last week by Sir Victor Horsley, who drew some valuable present-day lessons from the life work of the famous Liverpool surgeon, of whom he said that he had tried to live up to Pasteur's scientific ideal that "the doctor must consider what people will say about him a hundred years hence and not trouble himself about the blame or praise of to-day." Sir Victor Horsley pointed out that Mitchell Banks, Edinburgh born and bred, was the child of a school celebrated in particular for the academic recognition of anatomy, while Goodsir, whose pupil Mitchell Banks was, had also comprehensive views of medical work in its relations to the social life of the people. These things undoubtedly conduced to the double development of Banks's work at Liverpool, whereby during his tenure of the chair of anatomy that department became the most flourishing in the old University College of Liverpool, while later as a professor in the new University his work showed deep sympathy with the aims of social science. The two subjects of Mitchell Banks's work chosen by Sir Victor Horsley for particular mention as honourably associated both with the name of Banks and with the record of Liverpool surgery, were the treatment of cancer and the treatment of hernia. Sir Victor Horsley showed that when nearly 40 years ago Banks published in detail the results of his work on cancer of the breast he dispelled a sort of intellectual fog by establishing two principles—viz. (1) that the whole of the breast tissue must be removed because even in parts of the gland not obviously the seat of active cancer there were nevertheless changes which must be regarded as pre-cancerous; and (2) that all the lymph glands in relation to the mammæ should be removed on the ground that it is impossible to determine at the time of operation, when they appear to be normal, that they are not really infected. Mitchell Banks was a motive force in dispelling the fatal error of incomplete operating in such cases, and well deserves to receive the credit due, though even now, Sir Victor Horsley considers, the necessary procedure is not followed in its entirety except by a few surgeons. In another direction, with what Sir Victor Horsley aptly terms "practical prescience," Mitchell Banks seized upon a common infliction imperfectly treated, and was untiring in his efforts to ensure a real facing of the conditions, so that surgical methods could be adopted, based alike on anatomical knowledge and well-informed prognosis. Mitchell Banks was very early to see that the proper treatment for hernia is as a rule the radical operation, a point of view which to-day seems merely reasonable, but which, when Banks was a young man, represented dangerous speculativeness. The radical cure of hernia could not be regularly employed, save as an adjunct to an operation for the relief of strangulation, until Lister had freed operative procedures from the risk of infection, but when freedom from sepsis was ensured it became wrong to regard the application of a truss as a satisfactory measure. Sir Victor Horsley pointed out in a vigorous plea for thorough surgery that the only real pathogeny of hernia is that formulated by Mr. R. Hamilton Russell,[1] who has taught that a preformed sac is the causal factor of hernia; in complete line with this teaching is Mitchell Banks's procedure for radical cure—namely, removal of the sac with restoration of the continuous peritoneal surface and protection of the hernial area by closure of the femoral canal. Sir Victor Horsley's address was both a fitting testimonial to a great surgeon and an outspoken plea for thoroughness in our surgical methods.

OLD FIREARMS AND GUNSHOT WOUNDS.

EARLY Arab historians call what is credibly believed to have been gunpowder "Chinese snow" and "Chinese salt," and the Chinese are supposed on good authority to have used explosives and some sort of cannon centuries before the Christian era. Their invention was known as "Greek fire" to the Byzantine Greeks, then to the Arabs, and it reached Western Europe in the thirteenth century. Firearms have been discussed by many writers from the time of Leonardo da Vinci onwards. One of the early classic authorities on wounds in war, including gunshot wounds, is the quaint Hans von Gersdorff, whose "Feldtbuch der Wundartzney" was printed in the ancient free city of Strasburg in 1516 and again in 1526. Von Gersdorff's curious black-letter pages, written in a German closely resembling the modern *Strasbourgeois*, have almost a pacifist tendency when compared to the ferocious record of modern warfare, with its howitzers built into concrete platforms, its holocausts of slaughter and appalling wounds. The "Wound Medicine Book" deals largely in rude woodcuts, and we are shown a soldier, a rough man suffering great pain, as the ancient engraver has managed to portray, from whose chest an arrow or bullet is being withdrawn by an army surgeon. A soldier holds the sufferer by the shoulder to steady him on his three-legged stool, while the surgeon, distinguished by black shoes and a slightly more elaborate costume, is performing the operation. The patient might be the Valentine of "Faust." The same kind of cut reappears in William Clowes's classical work on surgery in the time of Queen Elizabeth, but the costumes in this latter case seem to date from the fifteenth century. Von Gersdorff, who, by the bye, does not seem to have been a noble, for he rejoiced in the peasant nickname of Schielhans, is more explicit on the subject of arrow wounds than of gunshot wounds. When the subject has been wounded by an arrow there are three ways of treating him. Either, he says, the shaft must be pulled out bodily, which is risky, or driven right through to the other side, which is very fatal, unless some fleshy portion of the patient only is involved. An arrow through the buttock, for instance, may be pulled right through. In a third case, when the arrow remains fixed, several courses may be adopted. The wound may be enlarged with a scissors or knife or, better still, it may be allowed to grow corrupt, when in the general softness the arrow-head will come away of itself! In dealing with gunshot wounds the procedure recommended is similar, except that it is not suggested that the bullet should be pushed through the wounded part. Probing by sounds, and inunctions of oil with the hand, are recommended, and the wound may be enlarged by cutting instruments or by the old now disused instrument called "the dilator," which Schielhans calls the "hole-maker" (*loucher=locher*). The smashing wounds caused by modern projectiles are not contemplated by this old writer, whose picture of a bullet shows us a missile only about three inches in diameter striking a man's leg. The old field-pieces of that age were rarely very large. One only is represented by von Gersdorff. It is about six feet long and is being used in a battle between men armed with lances. In Francisco Rota's book on "Gunshot Wounds," published at Bologna in 1555, there is a design on the title page representing small field-pieces, some of which have solid non-spoked wheels and the arquebuses of the day—huge muskets, propped up upon tridents. The arquebus only came to be shot from the shoulder after it had been for long shot as a cannon from a stand, as Robinson Crusoe shot his fusils. The Germans, curiously enough, are said to have been the first to fire the arquebus from the shoulder. They are now said, on all hands, to fire from the hip, and it is possible that the arquebus being very heavy and awkward in make was thus anciently fired. A remarkable point that may here be noted is that the ancient descriptions of the effects of a severe gunshot wound do not differ from those in the modern text-books. In both ancient and recent writers there is the same account of the trembling fit, the complaint of cold, the pallor, the suddenly lowered pulse after a bullet has gone home. William Clowes holds almost this modern language in the time of Queen Elizabeth, and the dreary theme has been elaborated by the master hand of Tolstoi in "War and Peace." We, at the present, realise all these descriptions to a strange degree. And old von Gersdorff, who wrote of little battles where few fell, on that terrible tortured borderline where now the hugest battle of all time is raging, is a notable and sad reminder to us that civilisation since his time has brought its losses as well as its gains.

CHINA TEA.

IT is well known, of course, that China tea contains much less tannin than the teas of India and Ceylon, but, as we have pointed out, if the infusion contains theine and tannin in a certain ratio, neither of these would appear to be present in the free state. The amount of theine upon which the restorative qualities of tea depends in all three teas is much the same. The existence of three kinds of tea enables the consumer to choose the one which suits him, and his judgment is commonly based on popular opinion as to flavour. The Board of Trade returns show that the consumption of China tea in the United Kingdom for the first eight months of the present year exceeded by 4,000,000 lb. that for the corresponding period of 1913. Notwithstanding the temporary insecurity of the Eastern seas, the supply of China tea, we understand, which has reached London is large enough to enable the importers to sustain the market at normal rates, so that the increasing number of consumers of China tea will not suffer in price. The reason, no doubt, for the increasing popularity of Chinese tea is that the Chinese Government is becoming alive to the need of modern methods of treating the plant. It is picturesque, if nothing else, that there should be a chance of our reverting in these days to the old-fashioned growths which held their own at the tea tables of Queen Anne, when the fluid was called "tay" and the leaves cost £1 a pound.

[1] The Saccular Theory of Hernia and the Radical Operation, THE LANCET, Nov. 3rd, 1906, p. 1197.

THE ACTION OF THE IODIDES ON THE HEART AND BLOOD-VESSELS.

THOUGH the iodides are among the most frequently used drugs of the Pharmacopœia their mode of action is still imperfectly understood. Thus in arterio-sclerosis some suppose that they promote absorption; others that they decrease the viscosity of the blood; still others, such as Potain, that they lower blood pressure by acting on the heart and vaso-motor nerves. On the other hand, Romberg, Kraus, and Dr. James Mackenzie could not find any influence on the heart or arterial lumen. Experiments on animals have been equally contradictory. In the *Johns Hopkins Hospital Bulletin* for September Dr. David I. Macht has published an important research. Previous observers only investigated the action of the iodides as such, without paying attention to the rôles played by their constituents, iodine and potassium or sodium. Dr. Macht prepared Locke's solution according to the following percentage formula: $CaCl_2$, 0·024; KCl, 0·042; $NaHCO_3$, 0·03; NaCl, 0·9; dextrose, 0·1. In order to study the potassium constituent of KI he replaced part of the NaCl by an equimolecular weight of KCl. In order to study the action of the iodine constituent he replaced part of the KCl by an equimolecular weight of KI. The solutions were perfused through the abdominal aorta of a frog and the outflow from the veins of the legs was registered on a revolving drum. The results were as follows. The I ion markedly constricted the vessels, the K ion relaxed them, and the Na ion had little or no effect; if anything it increased the vascular tone. The effect of injections of the salts KI and NaI was a combination of the effects of their component ions. NaI distinctly constricted the vessels. KI produced either no effect or a slight increase of tone, showing that the I effect balanced or overbalanced the K effect. On the frog's heart the K ion had a very depressing action, causing speedy arrest in diastole. Iodine was an active stimulant and Na had a slightly tonic effect. The effects of KI and NaI could easily be explained by the effects of their components. NaI stimulated. KI showed the predominating influence of the K ions; weak solutions produced slowing and weakening and stronger solutions arrest. Finally, experiments were made on the blood pressure of intact animals. Locke's solution injected in quantities of 5 c.c. per kilo. produced no appreciable change nor did NaI or KI in small doses. Large doses of NaI produced no effect or a slight tendency to rise; of KI, a marked fall. The latter was due to the K ions, for a similar effect followed substitution of KCl for NaCl in Locke's solution. When the effect of I ions was studied by substitution in Locke's solution, contrary to expectation, no rise in blood pressure was observed. The explanation was furnished by an observation made many years ago by Boehm, who showed that considerable quantities of iodine could be injected into an animal without producing a rise in blood pressure, because the iodine combined with the proteids of the blood. The practical conclusion follows from these experiments that when iodides are given to depress the circulation, as in aneurysm, it is not indifferent which iodide is chosen. It also follows, as far as experimental evidence goes, that the iodides have no special virtue in lowering blood pressure, but that the effect is entirely due to potassium, and might even more readily be obtained from other potassium salts. In this connexion the recent summary by Schwalbe of the views of German clinicians is interesting; the weight of opinion is unfavourable to the use of iodides in arterio-sclerosis.

THE RECLAMATION OF THE CAMPAGNA.

MR. L. VILLARI wrote an article on this subject in the *Edinburgh Review* recently which is of considerable medical interest. The Campagna is a congeries of hummocks rising into hillocks, intersected by *fossæ* either stagnant or dribbling their way into the Tiber. How is it that this should be the true description of an expanse of soil which was once famed for vegetative energy, and which, in response to cultivation, was covered with patrician residences and surrounded with gardens over which Pomona and Flora seemed in person to preside? How is it that a tract of country once a favoured health resort should have degenerated into a fever preserve, repelling that occupation which is the first condition of its rehabilitation? To these questions Mr. Villari gives an answer, which, we are happy to gather, is but the prelude to an independent treatise in which not only the "decline and fall," but the rise and "Risorgimento" of the Agro Romano will be set forth in full and authoritative detail. Meanwhile, views of the origin of one of the most characteristic phases of the Campagna, its unhealthiness from "malaria," are gaining ground which imply that insect life, in some of its most pernicious developments, is not the *causa causans* of the "malaria" in question, but is itself a symptom of a deeper pathological coefficient without which the said insect life would cease to exist. The Poet Laureate of Nature-study, in a magnificent episode of the Georgics, goes down to the root of the matter in that one most significant phrase—"justissima Tellus," a phrase interpreted by one of his best commentators in this sense: "Justissima, quippe quae creditum (semen) cum foenere reddere solet" (wont to pay back with interest the seed entrusted to it). Left derelict, or deprived of its proper treatment, the soil avenges itself by an unerring retribution—its unutilised vegetative energy taking the form (in Léon Colin's expression) of a "telluric respiration" which, infecting the atmosphere, evokes the insect (the scavenger of the air) which gives back the poison it absorbs. Wherever cultivation has done justice to the soil, rendering the "telluric respiration" healthy, the insect disappears and with it the "malarious" infection. To this Mr. Villari bears emphatic testimony, showing how the "bonifica" (reclamation) now in progress under Government is, precisely in those localities where it has been thoroughly practised, the prelude to the extinction of the insect (deprived of its pabulum), and, coincidently with this, the disappearance of the "malaria" and of the fever it induces. In other localities, where the "bonifica" is still to be effected, the State provision of quinine and wire gauze in the dwellings have had most salutary uses—the notable reduction of sickness, as shown by Mr. Villari's figures, being a result as incontestable as it is gratifying. But these are preventive measures, and the money expended on them, while a heavy draft on a not very affluent exchequer, would be commendably employed in reinforcing and accelerating the "bonifica" already yielding such a rich and perennial return. The appropriate utilisation of the vegetative energy by scientific agriculture—in a word, the restoration of the Campagna to the salubrity and the amenity it enjoyed under the Antonines—such is the prospect to which Mr. Villari invites us in the article above referred to, a prospect, moreover, of which we are promised a fuller fruition in the treatise on which he and his coadjutors are now engaged.

CARRIAGE OF POLIOMYELITIS INFECTION.

IN a report recently issued by the Local Government Board[1] Dr. H. A. Macewen gives the facts as to the distribution in place and time of the 56 cases of poliomyelitis known to have occurred during the summer and autumn of 1913 in Barrow-in-Furness and the wide area, including much of Westmorland, which lies between Barrow and Appleby. Groups of cases, amounting to 30 in all, occurred in Barrow between the end of March and the beginning of August; from July to the end of the year the disease ceased to appear in Barrow, but odd cases or small groups of cases came to notice in places within a 30-mile radius, and even beyond. Within Barrow the affected houses were in some instances close together, and some associations, direct or remote, could be traced between the persons attacked. In the first group of invaded dwellings in Barrow "the child No. 1 shortly before falling ill on March 23rd played with the child No. 3, the onset of the illness of the latter being some time in April, though the exact date could not be ascertained. The children Nos. 10 and 20 in Barrow Group No. 2 resided in the same street within a few doors of one another, and it was customary for them to play together before the first child fell ill. ...... The mother of child No. 8 in the Barrow Group No. 1 had often been in the house of child No. 3 during the course of its illness and before her own child fell ill"; and so it was with other cases within and outside Barrow, where not infrequently circumstances were detected which would have permitted the inference to be drawn that an infection, with a variable incubation period, had been carried in some way from one known case to another. Against all such theories of personal carriage of infection, however, Dr. Macewen places the fact that there was no single instance of multiple cases in the same house amongst the whole of the 56 cases investigated. The other children of the family, brothers and sisters, living in the houses where cases occurred amounted to 139, the great majority of ages being under 10. It is difficult to reconcile the supposition that the disease had been spread by direct or indirect personal carriage of infection with this absence of attacks among other members of the families, unless, perhaps, on the hypothesis that the total number of persons in this area who were susceptible to attack by poliomyelitis was very limited indeed. The suggestion that the infecting organism is introduced by biting flies has often been made, and on the hypothesis that bites from an infected fly are necessary the limitation of cases to single members of a family would be intelligible. But before such an explanation can pass out of the realms of mere conjecture the fly must be identified, and some evidence be produced as to whether the virus is carried by the fly from human case to human case, or whether it is otherwise acquired by the insect. It is noteworthy that as a rule there was no history of concurrent illness among members of the family of the households attacked, although Barrow was visited in the spring of 1913 by a severe outbreak of influenza, affecting a large number of persons and causing several deaths. Information on many other points is set out and tabulated by Dr. Macewen, and though it leads to no definite conclusions as to the mode of spread of poliomyelitis, the report is of distinct value as indicating the conditions of occurrence and distribution of the disease which require to be explained by any satisfactory theory of its causation.

THE LOCAL THERAPY OF TETANUS.

A large number of cases of tetanus have been reported as occurring among the soldiers wounded at the front, and it may not be out of place to draw attention to an article on this subject by Dr. G. Vitello published in *Il Morgagni* of July last. The writer urges that, although tetanic spores resist the action of antiseptics, they are not of themselves capable of producing the intoxication. In order that they may be put into a condition to secrete the toxins it is necessary for them to be bacterially associated with other micro-organisms which, being much less resistant to the action of antiseptics, can be easily destroyed, even by weak solutions. It is presumable, therefore, that in the disinfection of a tetanic wound the micro-organisms which are the most efficiently destroyed are not the spores which resist for a long period the action of the antiseptic, but those micro-organisms which are found with them in the wound and which under natural conditions confer on them the faculty of virulence. If, on the other hand, the spore is alone and without the collaboration of these germs, it is not capable of secreting the toxins and remains inoffensive in the wound. It has, moreover, been experimentally demonstrated that rigorous antisepsis of wounds during the period of incubation is often successful in aborting the disease in its pretetanic phase. The use of tincture of iodine is to be strongly recommended for this purpose and Formiggini, in a case of tetanus which had developed subsequent to a wound of the upper eyelid and which he had treated by suitable disinfections with tincture of iodine, showed that in the bacteriological examination of material taken from the wound ten days after its occurrence, a bacillus was isolated, having cultural and morphological characters similar to that of Nicolaier, but which was not pathogenic to guinea-pigs and rabbits. Hence it may be argued with some degree of probability that tincture of iodine used in tetanic wounds has the property of rendering innocuous the specific micro-organisms, or of ensuring that should tetanic phenomena unfortunately make their appearance they will show themselves in a mild form. Mention of another method of treatment must not be omitted—namely, the local sero-therapy practised for more than ten years in Italy by Professor Tizzoni. Sero-therapy, which constitutes the most scientific means of combating tetanus, may also be of great value in its local cure. A. Calmette infected wounds made on various parts of the body in ten guinea-pigs by a mixture of dust and earth containing fresh tetanic spores. While the control animals were seized with fatal tetanus in from four to six days, the ten which were treated two to six hours after infection with the application of dry tetanic serum to the wound remained immune. Professor Tizzoni from his experiments has proved that the local action of the serum is much more efficacious than its general action, and he advises always that injections of antitetanic serum should be made as near as possible to the wound. When the wound is open he recommends plugging it with gauze soaked in the serum so as to attack more deeply and directly the parts first assailed by the poison.

[1] Reports on Public Health and Medical Subjects, No. 98. London: Wyman and Sons, Fetter-lane; Edinburgh: H.M. Stationery Office; Dublin: E. Ponsonby. Price 8*d*.

THE LESIONS OF THE THYROID GLAND IN GRAVES'S DISEASE.

THE April number of the new *Annales de Médecine* contained an instructive paper on the lesions of the thyroid gland in exophthalmic goitre by Dr. Gustave Roussy and Dr. Jean Clunet of Paris, which it is not too late to introduce to our readers. It serves to illustrate the difficulty of determining the significance of morbid changes and of "following the trail" where these lesions are multiple and multiform. It has often been taught that no histological criterion exists whereby to distinguish between simple goitre and exophthalmic goitre; chronic inflammatory changes, sclerosis, colloidal alterations, adenoma, and interstitial haemorrhages are described as occurring in either. In this paper, which is based on a considerable number of personally observed cases, the writers show that in exophthalmic goitre the lesions are of three types. 1. Epithelial hyperplasia, exactly comparable to what they have seen as compensatory hyperplasia in the thyroid of dogs, following on experimental incomplete thyroidectomy. The hyperplasia is recognised by the presence of cylindrical cells, overgrowth of acini, and pale, ductile colloid. It is only in exophthalmic goitre and experimental compensatory hyperplasia that these histological changes are found spreading over the whole gland; in senile thyroid sclerosis and in slowly progressing simple goitre they may be found in small local isolated patches; hence, if not strictly specific, their extension over the gland is highly characteristic. 2. Little islets of eosinophil cells are found in a very large percentage of thyroids in exophthalmic goitre and are regarded by the writers as forming an important cytological feature of the disease. 3. Masses of lymphoid cells are extremely common in exophthalmic goitre, but not specific; they occur exceptionally in other forms of thyroid inflammation and in other goitres, but never to the same extent as in Graves's disease. These latter cytological alterations are not present in experimental compensatory hyperplasia, a fact which suggests that in Graves's disease the condition is not so much one of simple hyperplasia as of dyshyperplasia. As for the vexed question whether the affection is a primary disease of the thyroid gland, the attitude of the writers is that the disease is primary in the thyroid, and that visceral, nervous, and muscle changes found at necropsy, especially those of the sympathetic, are secondary lesions due to the action of thyroid toxins, with the exception, however, of alterations of the thymo-lymphatic system. The suggestion is put forward that these are of some importance in the production of the syndrome and that they are the direct sequel of the infection originating the whole morbid process. As long as this infective element is in process of evolution, sodium salicylate, quinine, arsenic, and mercury are of value in treatment. Once the dyshyperplasic state has set in "hémato-éthyroïdine" and Mœbius's serum are useful. Partial thyroidectomy is of less value than slow progressive experimental atrophy, which can be produced satisfactorily by radiotherapy.

TUBERCULOUS BRONCHIAL GLANDS IN CHILDHOOD AND ADULTS.

THE different types of pulmonary tuberculous infection in children and adults are, of course, familiar—how, in the former, gland infection dominates the clinical picture, and how, in adults, the general lung parenchyma mainly suffers. The explanation of the cause of this difference is not simplified by the later researches of Kuss, Albrecht, and Ghon, which suggest that, even in children, bronchogenous infection is the rule, and that the initial lesion in them is not primarily glandular, but situated in the lung. The claim that the glandular infection is explained by the different route of the tubercle bacilli in children is thus opposed by these researches. If, then, at both ages the path of infection is similar, why is the site of the lesion so different in each? Dr. E. Rist[1] records some pathological observations which help to throw light on this question. In the first place, he finds that post-mortem examinations on adults, who when young had gland infection, now show no evidence in the bronchial glands of the past disease; and, further, both in these cases and in adults who suffer from pulmonary tuberculosis *de novo* the glands are but little affected, and this even if there has been a long phase of caseating lung tuberculosis preceding death. Again, the glands show in such cases no abnormal macroscopical appearances. Microscopically, true, there may be small evidences of gland transformation indicative of the past infection, but such hyaline degeneration does not prevent the rest of the gland from reacting to the later infection. And that they can so react is shown by their inflammatory response to such a condition as pneumonia. That they do not so respond to added tuberculous infection shows that their manner of response has in some way been specifically altered. Dr. Rist suggests from these facts that this freedom of glandular response to tuberculous infection is an obvious illustration of what Professor von Pirquet calls allergy. It is the same condition which protects the mucous membrane of the mouth and tongue of the consumptive patient against tuberculous infection; and, similarly, the skin. Caseation of the bronchial glands, then, on this showing, is not a specific character of childhood, but of primary tuberculous infection. If, on the other hand, pulmonary tuberculosis of the adult is, as a rule, not associated with such a condition, it is not because the lymph glands of the adult are different from those of the child, but simply because pulmonary tuberculosis of the adult is due to a *re*-infection, and the glandular response thereto has been altered. The argument is of considerable interest.

SIR WILMOT HERRINGHAM, M.D., Vice-Chancellor of the University of London, will take the chair on Tuesday next, Oct. 20th, at 8.30 P.M., at the first of a series of six lectures on "Louvain and its University," which will be delivered in French at University College by Professor L. Van der Essen.

THE Harveian oration will be delivered before the Royal College of Physicians of London by Sir Richard Douglas Powell, Bart., at 4 o'clock precisely on Monday next, Oct. 19th.

---

THE CLAIMS OF BRITISH SPAS.

(*Continued from p. 863.*)

III.—HARROGATE.

THE name of Harrogate will always be associated with its evil-smelling sulphuretted hydrogen waters, in spite of the very important developments which have been made in regard to methods of treatment which are independent of the use of those waters.

The sulphur waters of Harrogate are unique in composition; their exact equivalent is not to be found on the continent nor among other sulphur springs known in this country, as at Strathpeffer in Scotland and Llanwrtyd and Llandrindod in Wales. The quantity of sulphur present either in the form of sulphuretted hydrogen or of sulphide of sodium exceeds that of such well-known sulphur waters as Aix-la-Chapelle or Baden. Abroad, however, the sulphur springs are generally thermal, while those at Harrogate are cold, and this fact probably accounts for their superiority in sulphur constituents. The old sulphur well at Harrogate contains no less than 37 cubic centimetres of sulphuretted hydrogen (H_2S) per litre and 0·07 gramme of sodium sulphide. There are present also 12·7 grammes of sodium chloride and distinct quantities of barium chloride, which in view of the powerful action of this salt cannot be disregarded. Not all the springs show this composition, and there are no less than 80 mineral springs at Harrogate, of which 16 or 17 are used for internal administration and the remainder for bathing purposes.

Last year the completion of some important extensions to the spa establishments at Harrogate was accomplished, which promise to bring it into formidable competition with the health resorts abroad. A few facts will justify this conclusion. As we reported last year,[1] owing to the accommodation of this popular resort having become inadequate, a commodious annexe was completed which has proved a great convenience to its increasing patrons. In the height of the season no less than 2700 glasses of water were served each morning before 9 o'clock from the historic spring known as the old sulphur well. No less than a quarter of a million sterling has been spent on this hydropathic station during the past 40 years, and the returns of 1912 show that over 500,000 tickets were issued to water drinkers and 160,000 for treatment. There is a very interesting fact underlying the good medical work done at Harrogate. Not very many years ago the town of Harrogate was losing something like £2000 a year on its baths and wells, but the authorities did not let this discourage them, and they have been rewarded, for now there has been paid off in redemption of debt and in interest the handsome sum of £70,000, and at the same time £11,500 have been apportioned towards the relief of rates. These facts speak eloquently of the admirable efforts on the part of the authorities at Harrogate to bring the medical and social advantages of their health centre into the sphere of public patronage enjoyed by watering places abroad.

The nucleus of attraction at Harrogate is a fine natural endowment of medicinal waters, and the cases for which they are suitable are well known. The treatment at Harrogate is applied to those cases which derive benefit at such places as Aix-la-Chapelle, Homburg, and Kissingen. Amongst the cases may be included chronic dyspepsia, constipation, congestion of the portal system, functional hepatic disorders, and so forth. Chronic gout and rheumatism receive relief from both internal treatment and a course of baths. No claim is made on the score of the natural waters being radio-active, though events tend to show this to be the case, and according to modern views it appears to be recognised that radio-activity is of undoubted assistance in promoting the therapeutic action of the naturally occurring chemical ingredients such as are found in Harrogate waters.

We have often pointed out that at our home health resorts treatment is too usually confined to the use of waters, whereas the régime insisted upon in continental methods enforces, in addition to a regular course of baths or of drinking the waters, a rigorous control over general and dietetic habits. This lesson, we believe, has been learnt at Harrogate, and, more than this, the strict routine so enjoined receives the relief required in the shape of social amusements in an environment of healthy air and attractive scenery. Harrogate may fairly be placed amongst the bracing watering places inasmuch as it is situated at an altitude of 600 feet or so above sea level, and the air is dry owing to the environment being free from woods, rivers, and lakes, the surroundings, in fact, being the well-known moors and dales of the West Riding. There is no doubt that treatment is well assisted at Harrogate, as at others of our health resorts, by favourable climatic conditions.

First-class facilities have been provided at Harrogate for extra hydropathic treatment. In addition, for example, to the variations in the methods of applying the natural waters, as in mud baths, sprays, irrigations, and internal administration, relief is offered by a great variety of electrical, thermal, and mechanical appliances. As we have previously reported, the appliances for electrotherapeutics are very complete. There is a fine installation of hydro-electric baths and every precaution is taken to make accident impossible. There is an independent electrical supply, and the baths are so insulated as to give a resistance to earth practically amounting to infinity. Every form of current is readily available. Static electricity is supplied by a high-speed ebonite plate machine, which is reported to give satisfactory results. High-frequency electricity is obtained from about half a dozen sets of apparatus in various parts of the station. It is used through vacuum electrodes for a variety of conditions, for the production of ozone, and for bipolar massage, a form of treatment that has given good results at Harrogate. Diathermy is in full employment and the results are encouraging. Then there is the apparatus for the treatment of obesity by the method suggested by Bergonié. A faradic current is employed, and by means of several electrodes distributed over the body according to a definite scheme, the principal muscles are made to go through a series of rhythmic contractions against a load that is adjustable by the use of sandbags. Exercise is thus obtained without fatigue, and a loss of weight is observed from the beginning of the treatment as well as an improvement in general health. The installations at Harrogate include complete equipments for Berthollet treatment, sulphur and needle baths, the Plombières bath and douche, Vichy massage douche, the liver pack, the oxygen bath, the Schwalbach bath (natural ferruginous water), the brine bath, inhalation systems, throat sprays, nasal douche, radiant heat and light treatment, cataphoresis, massage, and, in fact, all the accessories which are now recognised as forming part of the scientific equipment of an establishment claiming to be progressive in the different branches of hydropathic practice.

---

[1] THE LANCET, June 14th, 1913, p. 1685.

Finally, the social attractions at Harrogate are well organised, and the medical routine is relieved by recreations provided in sports and in a well-appointed concert hall and theatre and other places of amusement.

Harrogate, in short, furnishes a decisive answer in the affirmative to the question as to whether these things can be done at home in the same efficient manner as is the case abroad.

"THE LANCET" HYGIENIC TESTS FOR GAS FIRES.

WE continue to receive from well-known makers of gas fires models for submission to THE LANCET test for hygienic efficiency. The spirited way in which the industry has taken the matter up, and its determination to render this method of domestic heating free from hygienic reproach, are very satisfactory, and we are glad to have played a part in the work. But we do not forget, and have pointed out before, that much to their credit the movement was begun by a firm of gas-fire makers—namely, Messrs. Davis and Co., of Luton, who introduced the shadowgraph, an apparatus designed for detecting the escape into the room of water vapour from the fire. Its action depends upon the deposit of moisture upon cooled glass brought in front of the canopy of the stove.[1] This invention has done excellent service, and it inspired the introduction of another test which was devised in THE LANCET Laboratory. The test is a chemical one and admits of simpler execution. It consists in allowing a small amount of carbon-tetrachloride vapour to flow into the gas-air stream. A piece of chalk soaked in carbon tetrachloride is simply placed near the air inlet. The result is that a correspondingly small amount of hydrochloric acid gas is produced. If now a piece of sponge containing liquid ammonia be brought to points along the canopy of the fire, fumes of ammonium chloride will be formed if the products of combustion are escaping into the air instead of passing through the flue nozzle to the chimney. We have now examined over 25 models by this method since our first report was issued, and every one of them has passed the test satisfactorily.

The following fires were recently sent in by Messrs. Fletcher, Russell, and Co., of Warrington, and 134, Queen Victoria-street, E.C.: (1) Rosario; (2) Palermo; (3) Toledo; (4) Borneo; (5) Dee; (6) Dart; (7) Dove; and (8) Dane. All the fires were of modern design, and not one showed leakage of products of combustion when submitted to the test. The test was made in the open room both with and without a 2-ft. flue attached. The 2-ft. flue was not found to be necessary.

The Planet Foundry Co., Limited, of Guide Bridge, near Manchester, and 28, New Bridge-street, sent in the following fires: (1) No. 2 New Mars; (2) No. 2 New Venus; and (3) No. 2 New Saturn. These are well designed fires and evidently constructed with hygienic considerations in mind, since they all passed the test satisfactorily in the open room without a flue attached. We should like to make the suggestion, however, that the maximum consumption of gas in these stoves might with advantage be increased in order to extend upwards the incandescence of the "radiants."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on Oct. 8th, Sir W. WATSON CHEYNE, the President, being in the chair.

It was resolved, on the recommendation of the Museum Committee, to purchase the complete skeleton of an okapi.

It was reported that three attendants in the museum had enlisted and that the hall-porter had re-enlisted in the army, and it was resolved to pay them full wages for the next six months.

Sir RICKMAN J. GODLEE, on behalf of the committee on the annual report of the Council, submitted a draft copy of the report to be presented to the Fellows and Members at the annual meeting on Thursday, Nov. 19th next. The report was approved and adopted.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeon: P. M. May to the *Victory*, additional. Staff-Surgeon: A. F. Fleming to the *Victory*, for R.N. Division, Walmer. Surgeons: R. A. Rankine to the *Cyclops*, additional; K. H. Hole to the *Victory*, additional; and J. Barrett to the *Fisgard*. Temporary Surgeons: A. R. MacMillan, J. Rothwell, H. L. G. Foxell, P. B. Kelly, C. E. W. Lacey, A. A. Ballance, H. C. Waldo, and M. Onslow-Ford to the *Victory*, additional, for R.N. Division; H. G. Brown to the *Victory* for R.N. Division, Crystal Palace; L. R. Warburton to R.N. Division, Plymouth; C. Warner to the *Devonshire;* H. Wilks to the *Ganges;* and C. J. C. Faill to the *Victory*, additional.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel M. T. Yarr has been appointed Deputy Director of Medical Services for the London District.

Colonel Richard H. S. Sawyer is retained on the active list under the provisions of Article 120, Royal Warrant for Pay and Promotion, 1913 (dated Oct. 9th).

Major Harry A. Hinge to be Lieutenant-Colonel (dated Sept. 19th).

The undermentioned are granted temporary rank as follows whilst serving with the Duchess of Westminster's War Hospital:—Dated Sept. 27th: As Major: Charles Gordon Watson. As Captains: William Philip Sutcliffe Branson, Harold Pritchard, and Sydney Scott. As Lieutenants: John Southerden Burn and Dudley Macaulay Stone.

The undermentioned to be temporary Lieutenants:—Dated August 5th: Charles Ernest Lewis Burman. Dated Sept. 28th: Sydney Domville Rowland. Dated Sept. 30th: Lindsay Clive Smith, late Lieutenant, 4th Battalion, The Suffolk Regiment, Arthur Beeny Appleton, and Francis Caven Macdonald. Dated Oct. 1st: David Thomson, Eric Francis Wallace Mackenzie, Thomas Ebenezer Lawson, Frank Edwin Johnson, and William MacEwen. Dated Oct. 2nd: Charles George Lewis Wolf, Clayton Conyers Morrell, George Cuthbert Adeney, James Biggam, Cuthbert Scales, David Pottinger, John Richard Percy Allin, Leslie William Howlett, Wallace MacCallum Conley, and David Hardie. Dated Oct. 3rd: Richard Henry Cyril Gompertz, Arthur Baker Le Mesurier, Geoffrey Hadfield, William Alexander Todd, John McFadden, Robert Bertram Blair, Philip James Watkin, and Matthew Murphy. Dated Oct. 7th: Francis Frederick Muecke, John Nichol Clark, William Henry Laslett, Jeffery Wimpris Parker, and Malcolm Angus MacDonald. Dated Oct. 8th: Arthur Owen Playford Reynolds and Arthur Ainslie Hudson.

---

[1] This apparatus was fully described in THE LANCET of Feb. 7th, 1914.

SUPPLEMENTARY TO REGULAR UNITS OR CORPS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank: Joseph H. Baird, Clive A. Whittingham, John Alston, George H. Rossdale, and Robert Taylor. Second Lieutenant Phillip Jacob Gaffikin, from Princess Victoria's (Royal Irish Fusiliers) Special Reserve, to be Lieutenant.

The undermentioned Cadets and ex-Cadets of the Officers Training Corps to be Lieutenants (on probation): Albert Edward Woolfe Sandelson, John McKerchar, Walter Armstrong Elliott, and Trevor Braby Heaton.

The undermentioned to be Lieutenants (on probation): Frank Hutchinson Kennedy, Hugh Cochrane Storrie, and Thomas Graham Shand.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st London (City of London) General Hospital: Lieutenant-Colonel Sir Anthony A. Bowlby, C.M.G., to be seconded.

2nd London (City of London) General Hospital: Lieutenant-Colonel George H. Makins is seconded. Major Charles W. M. Moullin to be Lieutenant-Colonel.

South Wales Mounted Brigade Field Ambulance: Herbert Massingberd Pentreath to be Lieutenant.

1st Highland Field Ambulance: Captain John Hector Stephen and Captain Cuthbert D. S. Agassiz, from Attached to Units other than Medical Units, to be Captains. To be Lieutenants: Lieutenant James A. Morris and Lieutenant James E. G. Thomson, from Attached to Units other than Medical Units; and Daniel McDonald Grant and James Stewart McConnachie.

2nd Highland Field Ambulance: Lieutenant-Colonel Francis Kelly, from the Highland Clearing Hospital, to be Lieutenant-Colonel. Captain David Rorie, from the Highland Clearing Hospital, to be Captain. Quartermaster and Honorary Lieutenant Alexander Gibbon, from the Highland Clearing Hospital, to be Quartermaster, with the honorary rank of Lieutenant. Lieutenant Charles Cameron to be Captain. Lieutenants James A. Stephen, Alexander C. Mallace, and George Henderson, from Attached to Units other than Medical Units, to be Lieutenants.

3rd Highland Field Ambulance: Edwin Archibald Bell to be Lieutenant. Lieutenant Edwin Archibald Bell to be Transport Officer. Herbert Stuart Cleghorn to be Quartermaster, with the honorary rank of Lieutenant.

1st East Anglian Field Ambulance: Francis Ward (late Surgeon-Captain, 1st Volunteer Battalion, Suffolk Regiment) to be Captain.

2nd South Midland Field Ambulance: Albert Edward Peel McConnell to be Lieutenant.

1st West Riding Field Ambulance: Captain Harry B. Sproat, from Attached to Units other than Medical Units, to be Captain.

3rd West Riding Field Ambulance: The under-mentioned Captains to be Majors: James Mackinnon, Ernest Frederick Finch, and Charles Graham Murray. Lieutenant William N. W. West-Watson, from Attached to Units other than Medical Units, to be Lieutenant.

Eastern Mounted Brigade Field Ambulance: John Morgan O'Meara to be Lieutenant.

1st Home Counties Field Ambulance: Captain Joseph Ward to be Major. Arthur Thomas Falwasser to be Captain.

2nd Home Counties Field Ambulance: Lieutenant Bernard R. Billings to be Captain.

1st East Lancashire Field Ambulance: Lieutenant (Transport Officer) George Robinson Wattleworth, from Manchester Companies, Royal Army Medical Corps (Volunteers), to be Transport Officer, with the honorary rank of Captain.

2nd East Lancashire Field Ambulance: Lieutenant (Transport Officer) Charles Gordon Stoddart, from the Manchester Companies, Royal Army Medical Corps (Volunteers), to be Transport Officer, with the honorary rank of Captain.

Wessex Clearing Hospital: Major Clarence I. Ellis to be Lieutenant-Colonel.

Highland Clearing Hospital: Lieutenant-Colonel Alexander Ogston, from the 2nd Highland Field Ambulance, to be Lieutenant-Colonel. Quartermaster and Honorary Lieutenant James M. Munro, from the 2nd Highland Field Ambulance, to be Quartermaster, with the honorary rank of Lieutenant.

2nd London Sanitary Company: Lieutenant Percy N. Cave to be Captain.

Attached to Units other than Medical Units.—Captain John E. Molson to be Major. To be Captains: Captain Francis W. Goodbody, from the 3rd London General Hospital; Lieutenant Lee D. B. Cogan; and Cecil Arthur Ensor. To be Lieutenants: Cresswell Burrows, Humphry John Wheeler (late Surgeon-Captain, 1st Buckinghamshire Rifle Volunteer Corps), Francis Ryalls Eddison, Robert Evelyn Tissington Tatlow, and Herbert Connop.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8544 births and 4847 deaths were registered during the week ended Saturday, Oct. 10th. The annual rate of mortality in these towns, which in the three preceding weeks had been 15·1, 15·7, and 14·3 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year, further declined to 13·9 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 13·2, against a corresponding rate of 13·3 per 1000 in London. Among the several towns the death-rate last week ranged from 3·2 in Acton, 5·1 in Enfield, 6·2 in Gloucester, 7·8 in Lincoln, and 8·0 in Ilford, to 19·4 in Liverpool, 19·9 in Great Yarmouth, 20·2 in Warrington, 20·5 in Gateshead, and 21·1 in Southport.

The 4847 deaths from all causes were 119 fewer than the number in the previous week, and included 710 which were referred to the principal epidemic diseases, against numbers declining from 1437 to 877 in the three preceding weeks. Of these 710 deaths, 485 resulted from infantile diarrhœal diseases, 73 from measles, 57 from diphtheria, 47 from whooping-cough, 31 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·0, against 2·5 per 1000 in the previous week. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 1223, 1004, and 651 in the three preceding weeks, further declined to 485, of which 123 were registered in London, 49 in Liverpool, 32 in Birmingham, 20 in Manchester, 19 in Sheffield, and 13 each in Stoke-on-Trent and Nottingham. The deaths referred to measles, which had been 64, 50, and 61 in the three preceding weeks, further increased to 73 last week, and included 24 in London, 5 each in Birmingham, Birkenhead, Liverpool, and Sheffield, and 3 each in Manchester and Newcastle-on-Tyne. The fatal cases of diphtheria, which had steadily increased from 31 to 63 in the eight preceding weeks, fell to 57 last week; 17 deaths occurred in London, 5 in Birmingham, 3 each in Liverpool, South Shields, and Cardiff, and 2 each in Tottenham, Wolverhampton, Burnley, and Middlesbrough. The deaths attributed to whooping-cough, which had been 50, 40, and 50 in the three preceding weeks, fell to 47 last week, and included 11 in London, 4 in Bristol, and 3 each in Bradford and Hull. The deaths referred to scarlet fever, which had been 27, 23, and 29 in the three preceding weeks, further rose to 31 last week, of which 4 were recorded in London, 3 each in Birmingham and Warrington, and 2 each in Manchester and Salford. The fatal cases of enteric fever, which had been 20, 16, and 23 in the three preceding weeks, fell to 17 last week, and included 2 each in London, Portsmouth, Warrington, Hull, and South Shields.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased from 3071 to 4196 in the seven preceding weeks, had further increased to 4363 on Saturday last; 670 new cases were admitted during the week, against 551, 674, and 640 in the three preceding weeks. These hospitals also contained on Saturday last 1412 cases of diphtheria, 67 of enteric fever, 34 of whooping-cough, and 30 of measles, but not one of small-pox. The 1192 deaths from all causes in London were 99 fewer than the number in the previous week, and corresponded to an annual death-rate of 13·8 per 1000. The deaths referred to diseases of the respiratory system, which had been 110, 140, and 157 in the three preceding weeks, further rose to 175 in the week under notice, and were 52 above the number in the corresponding week of last year.

Of the 4847 deaths from all causes in the 97 towns, 169 resulted from various forms of violence, and 364 were the subject of coroners' inquests, while 1479 occurred in public institutions. The causes of 45, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, and in 68 other smaller towns. Of the 45 uncertified causes of death, 9 were registered in Liverpool, 7 in Birmingham, 3 in St. Helens, and 2 each in London, Southend-on-Sea, Nottingham, Blackpool, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1228 births and 698 deaths were registered during the week ended Saturday, Oct. 10th. The annual rate of mortality in these towns, which had been 15·9, 16·3, and 15·6 per 1000 in the three preceding weeks, rose to 15·9 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 14·4, against 13·2 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 10·2 in Kirkcaldy, 10·3 in Kilmarnock, and 11·0 in Falkirk, to 17·0 each in Paisley and Coatbridge, 18·6 in Aberdeen, and 20·7 each in Dundee and Greenock.

The 698 deaths from all causes were 11 in excess of the number in the previous week, and included 96 which were referred to the principal epidemic diseases, against 128 and 92 in the two preceding weeks. Of these 96 deaths, 54 resulted from infantile diarrhœal diseases, 14 from diphtheria, 13 from scarlet fever, 8 from whooping-cough, 6 from enteric fever, and 1 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·2, against 2·0 per 1000 in the 97 large English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had declined from 101 to 52 in the four preceding weeks, slightly rose to 54 last week, and included 26 in Glasgow, 10 in Dundee, 4 in Edinburgh, 3 in Aberdeen, and 3 in Clydebank. The deaths referred to diphtheria, which had been 4, 9, and 9 in the three preceding weeks, further rose to 14, of which 4 occurred in Aberdeen, 3 in Glasgow, 3 in Edinburgh, and 2 in Paisley. The fatal cases of scarlet fever, which had been 6, 12, and 12 in the three preceding weeks, were 13 last week, and included 6 in Glasgow, 4 in Aberdeen, and 2 in Dundee. The deaths attributed to whooping-cough, which had been 8, 13, and 13 in the three preceding weeks, declined to 8 last week, of which 6 were recorded in Glasgow. The deaths referred to enteric fever, which had been 3, 4, and 4 in the three preceding weeks, further rose to 6 last week, and comprised 5 in Glasgow and 1 in Greenock. The fatal case of measles occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 62, 64, and 71 in the three preceding weeks, further rose to 84 in the week under notice; 28 deaths resulted from various forms of violence, against 20 and 27 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 630 births and 355 deaths were registered during the week ended Saturday, Oct. 10th. The annual rate of mortality in these towns, which had been 19·9, 19·2, and 17·3 per 1000 in the three preceding weeks, declined to 15·4 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 16·9, against corresponding rates of 13·2 and 14·4 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 17·5 in Dublin (against 13·8 in London and 15·4 in Glasgow), 14·5 in Belfast, 12·9 in Cork, 12·7 in Londonderry, 21·7 in Limerick, and 22·8 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 12·3 per 1000.

The 355 deaths from all causes were 46 fewer than the number in the previous week, and included 53 which were referred to the principal epidemic diseases, against 92 and 53 in the two preceding weeks. Of these 53 deaths, 34 resulted from infantile diarrhœal diseases, 6 from whooping-cough, 6 from enteric fever, 4 from scarlet fever, and 3 from measles, but not one from small-pox or from diphtheria. The mean annual death-rate from these diseases was equal to 2·3, against 2·0 and 2·2 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 74, 71, and 41 in the three preceding weeks, further fell to 34, of which 14 were recorded in Dublin and 10 in Belfast. The deaths referred to whooping-cough, which had been 4, 9, and 6 in the three preceding weeks, were again 6 last week, and comprised 4 in Belfast and 2 in Cork. The 6 fatal cases of enteric fever were double the weekly average recorded during last quarter, and included 2 in Dublin, 2 in Belfast, and 2 in Ballymena. The 4 deaths attributed to scarlet fever, comprising 2 in Belfast and 2 in Waterford, were slightly in excess of the average recorded last quarter. The 3 fatal cases of measles occurred in Belfast.

The deaths referred to diseases of the respiratory system, which had increased from 35 to 58 in the four preceding weeks, fell to 56 in the week under notice. Of the 355 deaths from all causes, 107, or 30 per cent., occurred in public institutions, and 10 resulted from different forms of violence. The causes of 10, or 2·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 English towns the proportion of uncertified causes of death last week did not exceed 0·9 per cent.

THE offices of the Medical Sickness, Annuity, and Life Assurance Society have been removed to larger premises at Lincoln House, 300, High Holborn, London, W.C.

THE BELGIAN REFUGEES: THE QUESTION OF THE PROFESSIONAL CLASSES.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

AT the offices of the War Refugees' Committee in Aldwych I was favoured at the beginning of the week with a long interview by Lord Gladstone, who, as treasurer of the fund, has been unremitting in his efforts to organise the relief of the expatriated Belgians. What this means may be judged from the fact that the committee has by this time received at least 200,000 letters. Of these 20,000 contain offers of hospitality, and highly trained clerks have been employed in the work of indexing and keeping in order this voluminous correspondence. The allotting of refugees to the families that offer hospitality is a very delicate and difficult matter. The committee had already arranged for the reception of 3500 refugees when the figure of arrivals began to attain to more than 300 per day. This meant an influx too great for the committee to cope with, and the Government consented to take the matter in hand. The Metropolitan Asylums Board was ready to relieve the Refugees' Committee of the task of providing shelter for the new arrivals. 500 beds, food, and the necessary staff of attendants were made ready at the Edmonton Workhouse, an abandoned building which has now been refitted. A few days later the Metropolitan Asylums Board had 5000 beds ready, and the number can be increased. The rapidity with which this work was done was due in a great measure to the untiring efforts, continued night and day, of Mr. T. Duncombe Mann, Mr. G. A. Powell, and Mr. Kelly, clerk and assistant clerks to the Metropolitan Asylums Board.

The Need of Further Aid.

But it has to be borne in mind that this great assistance given to the War Refugees' Committee only applied at first to those who arrived in a denuded condition. By the end of September 7779 such refugees had been received, and the immense majority were of the peasant or agricultural labouring class. By the end of the first week in October the figure had reached at least 10,000, and the class of people coming over had begun materially to change. With the fall of Antwerp and the general German occupation of Belgium the refugees are now far more numerous and belong to all grades. Professional men and the aristocratic classes are largely represented, while it is certain that hospitality will have to be found for at least 100,000 persons at once. On the position of some of the better-class refugees Lord Gladstone spoke to me very earnestly. An increasing proportion of the refugees are highly educated, refined gentlemen and ladies who held good positions in their own country. Some were professors at universities or school teachers, doctors of law or of medicine, landowners, business men, shopkeepers, and even large employers of labour. Yet many of them when they arrived were absolutely penniless, and for the time being at least were so cut off from their homes and usual pursuits that they could not get any money. It is not possible to send them to sleep on a straw mattress laid on the floor of an abandoned workhouse, and vast efforts at better accommodation must be made. It is true that bedsteads are now coming in at the rate of 1000 per week, and that the mattresses have no longer to be put on the bare floors, but the general arrangements necessarily remain rudimentary from the modern point of view. Among the recent refugees, for instance, there was a judge of the Belgian High Courts, and many similar cases have been discovered, but they cannot all be recognised, and we may be sure that some of our unfortunate guests are not getting the reception we should all wish to give them.

The better class refugees are sent to hotels, where special terms have been made by the committee, and they receive board and lodging for 4*s.* 6*d.* to 5*s.* per day. It is obvious, however, that there is a limit to the funds the Refugees' Committee has collected. The opinion of the hospitality offered by the British nation to the Belgian people will be formed by the educated classes and not by the poor peasants accustomed to hard circumstances in their living. For the latter something akin to workhouse accommodation may fairly suffice—it is all we can offer our own destitute; but the educated classes who are momentarily in the situation, financially speaking, of paupers are entitled to expect other treatment. We must all try to see that they get it.

An Appeal to Medical Practitioners.

In these circumstances the Government must raise the scale of money allowance granted per head when dealing with people who are not paupers but refugees. The nation, there can be no sort of doubt, is anxious that the very best should be done so that our brave allies, who have suffered so terribly for their loyalty to their guarantees, may feel thoroughly satisfied with what British hospitality can do, little as it must be in comparison to their gigantic losses and miseries. In this the members of the medical profession can render signal service in Lord Gladstone's opinion. They have so wide a circle of acquaintances that it would be comparatively easy for them to discover families willing and able to offer hospitality to the better class of refugees. Since the fall of Antwerp the latter have been arriving in great numbers. Some 25 interpreters are at the stations to meet them, but when several hundred refugees disembark simultaneously some perforce have to wait. Fortunately, at Charing Cross and Victoria stations special inquiry offices and waiting-rooms have been provided. A meal is procured by the committee's agents, or a night's lodging is given, or a railway ticket to join some friend who is expecting the wayfarers, but there is not money enough to continue such help indefinitely. That is why no time must be lost in sending in offers of hospitality. Even with such help the question arises whether the Government will not have to organise a refuge of a higher class than the Alexandra Palace or the discarded workhouses where some of the expected crowds may be sheltered on a collective plan.

The Metropolitan Asylums Board is looking after the poor very well, considering the immense difficulties of the task. The trouble now is in regard to the rapidly increasing flow of refugees belonging to the higher classes, who could well be entertained as guests by the similar class in this country. The medical practitioner is in a good position to know who would be able and willing to lend such aid, and should communicate any information that may be of service to the War Refugees' Committee in Aldwych.

CANADA.

(From our Own Correspondent.)

Infant Mortality in Toronto.

The Department of Health, Toronto, has inaugurated a Division of Child Hygiene with Dr. Alan Brown and Dr. George Campbell as directors. With a population of 510,000 Toronto has 10,960 children under 1 year of age and 21,070 under 2 years of age. To care for these in times of sickness there are the following institutions. The Hospital for Sick Children, with a capacity of 250 beds, the baby ward containing 30 cots. This hospital has a well-equipped pasteurising plant capable of dealing with 150 gallons a day. Seven milk depôts throughout the city receive their supply from this source. The Infants' Home and Infirmary takes care of destitute children. For the year ending Sept. 30th, 1913, this institution took care of 289, of which 76 babies died during that year. Infants are no longer cared for without their mothers. St. Vincent's Home cares for destitute foundlings and illegitimate children and has an average of 100 cases in residence. The Haven and Prison Gate Mission last year furnished accommodation for 61 infants, 58 being illegitimate. The Sacred Heart Orphanage has an average number of 200 inmates. There are 42 licensed baby homes and 12 maternity homes under the supervision of the Department of Health. Four of the public hospitals maintain maternity wards and 1260 children were born there during the past official year. Four visiting nursing agencies do the bulk of the obstetrical work of the city; there are eight day nurseries or *crèches;* eight agencies carrying on settlement work; two women's organisations provide an ice fund; numerous private organisations for food and clothing; while there are six local organisations coördinating these philanthropies and preventing overlapping. Within a few hours of the reporting of a birth in the city one of the public health nurses, of whom there are 31, visits the home and investigates the surroundings of the child. If a doctor is in attendance nothing further is done; otherwise the mother is directed to bring her baby to a "well-baby clinic," of which there are ten. The appointments to these are made by the professor of pædiatrics of the University of Toronto and the medical officer of health. In 1915 it is expected to increase the number of these to 25, as it has been found essential to have one of these clinics to every 20,000 of the population. The Toronto Ferry Company supplies a floating sanatorium, and about 300 babies and mothers are taken out on each trip. A wet-nurse bureau is being established in connexion with the Division of Child Hygiene. In 1897, with a total population of 197,000, the infant mortality under 1 year from all causes was 664; in 1913, 1877.

The Prevention of Tuberculosis in Nova Scotia.

The Provincial Sanatorium at Kentville, Nova Scotia, is for early pulmonary tuberculosis cases and was established by the Government of that province in 1904. A weekly fee of $5 must be paid in advance. The balance to maintain the institution comes from governmental aid. Dr. A. F. Miller, the medical superintendent, in his ninth annual report states that during the hospital year ending Sept. 30th, 1913, there were 64 applications for admission, and of these 38 were accepted. At discharge 23 of these cases were apparently cured, 11 arrested, 2 improved, 2 only failing to respond to treatment. Two extra pavilions were added in the year with accommodation in each for 16 patients. Accurate records have been kept since 1910. Since that time 94 patients have received treatment; 59 of these are now working and well, 19 not working, 15 dead, and the condition of 1 unknown. There is great need in the province for free hospitals to which needy patients may go. The institution aims to help in the diagnosis of all cases in that province.

Toronto, Sept. 5th.

Correspondence.

"Audi alteram partem."

THE GOVERNMENT GRANTS FOR MATERNITY AND CHILD WELFARE.

To the Editor of THE LANCET.

SIR,—Your leading article of Sept. 26th has drawn attention to the admirable scheme of the Local Government Board as regards "Maternity and Child Welfare" issued as a memorandum last July. Its object is to link together the existing organisations and to organise new ones dealing with these subjects. Arrangements are to be made for: (1) Efficient *antenatal* advice and treatment by antenatal clinics, home visiting, and pre-maternity beds or wards; (2) for skilled attendance upon women during their confinements, and expert hospital treatment for parturient women with contracted pelves and other abnormalities or diseases; and (3) for treatment of mother and child after parturition, and subsequent systematic advice and treatment for infants and older children at suitable clinics or dispensaries, and by home visiting.

It will not be easy to link together all these agencies into a smooth efficient working scheme, but as the whole nation seems now alive to the value of infantile life and maternal welfare I feel sure it will eventually be accomplished.

To enable local authorities to form and extend the necessary organisations, the Local Government Board propose to give grants up to 50 per cent. of the approved expenditure of the more clinical and medical portions of the scheme, and similar grants from the Board of Education will be forthcoming for approved instruction, such as can be given on general lines in "schools for mothers," home visits, and by other kindred agencies. Personally, I see no reason why a hospital should not apply for a grant in aid of the expenses involved in the formation or extension of a definite antenatal clinic and laboratory with pre-maternity beds, for beyond the approval of the Local Government Board it would not involve, as I understand the scheme, any State supervision or control.

"Schools for mothers" will be developed through voluntary agencies or by local health authorities, and pregnant women will be there generally instructed in antenatal and natal hygiene, and if in any way thought to require help would be advised to consult either local practitioners of their own choice at an adjacent "maternity centre" or go to an antenatal clinic at a convenient general or lying-in hospital.

It is here where I think obstetricians all over the country can usefully help to make this scheme a success, whether they apply for the Government grant or not. At every such hospital where maternity cases are registered for attendance, an antenatal clinic is practically in existence, and has only to be extended to make its presence of immense service, not only to the women and unborn infants, but also to the students attending the clinics. Every such clinic should be in touch with a well-equipped laboratory. In such a clinic students would be taught how to recognise early toxæmia by urine testing and by clinical evidences, and they would be instructed in abdominal palpation and auscultation and the detection of pelvic abnormalities, and would learn the prophylaxis and treatment of the toxæmias and other complications of pregnancy.

Pregnant women in the general wards or in other out-patient departments of the hospital, with varied medical or surgical complications, could be notified to or transferred to the antenatal clinic, and a great mass of useful knowledge thus obtained. Occasional lectures could also be given. In some hospitals all this is already being done. In others, women are registered by the resident accoucheur, and but little effort is made to instruct students in a department of medicine now recognised to be of the greatest importance. Such a clinic should be distinct from the ordinary gynæcological out-patient department, so that students may realise that it is a special branch of study, and worthy of being treated as such, and the patients themselves would be in greater comfort and privacy.

This is the first time that any Government body has taken up the question of antenatal hygiene, and as it is the direct result of the importance now attached to the subject by medical men we should give it every support.

I am, Sir, yours faithfully,
AMAND ROUTH, M.D. Lond., F.R.C.P. Lond.
Manchester-square, W., Oct. 13th, 1914.

THE TREATMENT OF TETANUS.

To the Editor of THE LANCET.

SIR,—At a time when, unfortunately, tetanus is so common amongst those returning wounded from the front it seems advisable to direct attention to a form of treatment successfully employed by Mr. Oliver Atkey in a severe case at Khartoum. His paper appeared in THE LANCET of Jan. 18th, 1913, and the method consisted in producing general anæsthesia by the intravenous injection of a mixture of ether and paraldehyde given in normal saline solution. It was based upon the work of Noel and Souttar as regards the production of general anæsthesia. Their results will be found recorded in a paper published in THE LANCET of Sept. 21st, 1912.

I remember that in Mr. Atkey's case the tetanus bacillus was found, so that there can be no doubt as to the diagnosis, although, as a matter of fact, this presented no difficulties, for the case was a typical one. The initial dose was 5 c.c. of each drug in 150 c.c. normal saline, but this was increased later to 15 c.c. of ether and paraldehyde respectively, repeated from time to time. Mr. Atkey states that if he had another case to treat he would give larger doses. Considerable quantities of normal salt solution were also infused in order to rid the system as far as possible of the tetanus toxin.

Of course in tetanus antitoxin is our sheet anchor, but it is not always available, and very often it cannot be given in time. It therefore seems to me that Mr. Atkey's method merits a trial. It could conceivably be employed along with serum injections, but in the light of recent work by von Graff-Menochikoff this is open to doubt. It seems fairly free from danger, pulmonary œdema being the complication which has to be feared, but in tetanus one must take risks, for, as a rule, an untreated patient has little chance of recovery.

Mr. Atkey claims the following advantages for his method: 1. Very rapid anæsthesia. 2. The production of hypnosis as well as anæsthesia. The patient's strength is husbanded, pain is greatly lessened, and time is afforded for the absorption of nourishment and the employment of such other remedial measures as may suggest themselves. For similar reasons hedonal might be found useful. So far as I know it has never been employed in tetanus. Possibly, however, ether and paraldehyde are safer, though hedonal anæsthetisation has its advocates, and it certainly produces a marked muscular relaxation.

I am, Sir, yours faithfully,

Henrietta-street, W., Oct. 9th, 1914. ANDREW BALFOUR.

THE PREVENTION OF TETANUS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 3rd, p. 861, occurs a statement that cannot pass without comment. The statement is that the use of antitetanic serum "as a prophylactic remains yet to be more conclusively established." But its efficiency as a prophylactic has assuredly already been conclusively established. I am certain that if every wounded soldier collected by our ambulances received a prophylactic injection within 24 or 48 hours of the receipt of his wound we would not have a single case of tetanus. Instead of that we have the mortification of seeing reports of such cases each week. The evidence will be found in many experiments recorded. I need only mention two.

1. A horse infected with tetanus by Mohler and Eichorn died from tetanus within nine days. Of seven other horses infected at the same time with the same dose, and given antitetanic serum from 48 to 96 hours afterwards, not one died; two developed symptoms of tetanus but recovered. "From the results of these investigations it may therefore be concluded that 500 American units is a sufficient dose of antitoxin for use as a prophylactic even in cases where the infection has occurred four days prior to the injection of antitoxin."

2. In America, as a result of wounds received from explosions of fireworks during the "4th of July" celebrations, many cases of tetanus used to occur every year. In 1903, the first year when a strong effort was made to secure complete statistics, 406 deaths from tetanus occurred. The American Medical Association through its journal then started a campaign impressing on medical men the necessity of the prophylactic use of antitetanic serum in every case of burns and wounds. The cases have gradually dropped each year until in 1912 only six deaths occurred. The editor of the journal says: "We have made extensive inquiries into the treatment received by those injured in the '4th of July' accidents, and have yet to learn of a single case in which tetanus developed in a person who had early received a prophylactic dose of antitoxin." I am, Sir, yours faithfully,

Oct. 6th, 1914. A. T.

IMPERFECTIONS IN THE CUMBERLAND INFIRMARY.

To the Editor of THE LANCET.

SIR,—It is not apparent why Mr. H. A. Lediard, the senior surgeon, should have written the letter published in THE LANCET of Oct. 10th. My report on the Cumberland Infirmary relates mainly to administrative and domestic matters and only indirectly, if at all, to things medical. Hence the theatre, though not overlooked, claimed no special mention.

It is impossible for anyone to understand the questions raised unless my original report[1] is before them. That report was written as the result of requests made to me in August and October, 1909, by the chairman of committee and by an eminent member of the honorary medical staff. The latter enclosed in his letter a block plan of the whole of the infirmary, including the new extensions then in progress. It was not possible to comply with the request made earlier than June 20th last. I have always been interested in the welfare of the Cumberland Infirmary, having known several of its officers who have made high reputations and have risen to important positions in the hospital world. This feeling, and the letters just referred to, made me if possible more than usually anxious to make my report contribute to the bringing up of this important institution to the standard of an up-to-date modern hospital. I pointed out that "structurally the institution has been transformed for the better," but "administratively it has been changed sadly for the worse." That is what I found in the fewest possible words.

I have felt it to be a public duty to raise the following pertinent questions which go to the root of the matter. Has the personnel or character of the committee changed materially during the period in question? Has there been a gradual elimination of the former principles which led some of the most distinguished residents within the county to take an active part in the management? Has there been substituted for this element a large and increasing number of less responsible persons who have narrower views and are inclined to run the institution more on a sectarian or narrow basis? Is there an influence in the hospital which has been gradually acquired over all the departments by some one who has not a large and generous spirit, and who may, from many years' association, have got the affairs of this institution too much into his own hands? It remains to be seen whether the committee and governors of the Cumberland Infirmary will unite in an effort to make the administration of the infirmary up to date and smartly efficient.

In my report I suggested there was urgent need for an independent investigation at Carlisle, and the letter from Mr. Lediard confirms the practical value of this recommendation. There is evidence that Mr. Lediard and the infirmary authorities do not appreciate the responsibility of providing adequate recreation-room accommodation for the large staff of laundry-maids they employ. Further, that they do not realise the effects of the working of the present system of administration, which I emphasised and have good grounds to condemn. The question of a garden, and all I urged in regard to it, are not matters of appreciable cost but of sound management, and point to lost opportunities for expediting the recovery of the patients. The Cumberland Infirmary contains 140 beds, and Mr. Lediard's description of it as "a small provincial hospital" is, therefore, inaccurate. My criticisms rest upon the standard attained by a modern up-to-date hospital, whilst Mr. Lediard appears to be content with something infinitely inferior to it.

---

[1] See The Hospital, Sept. 19th, 1914, p. 677.

Mr. Lediard's letter is no answer to my report. He accuses me of "certain inaccuracies which mar the trustworthiness of his [my] statements," to wit, that the reconstruction has included (1) a new ophthalmoscopic room and (2) a new clinical room for ward work. He describes the former as a completely equipped ophthalmic department, and declares the latter has not yet been acquired. I must remind Mr. Lediard that the lithograph plan supplied to me from the infirmary contains the additions and alterations signed by the architect, and states on its face that these include D, a new clinical room, and K, a new ophthalmoscopic room. The inaccuracies, if inaccuracies there be, are therefore not mine, and if they mar the trustworthiness of any statements, as Mr. Lediard declares, they cannot be the statements in my report.

For the rest Mr. Lediard ignores the pertinent questions which my report contained, and contents himself by writing at length and at large in the apparent attempt to draw a herring across the scent. He declares and continuously insists that "we know how to adapt our expenditure to our means," an assertion which, for reasons set forth clearly in my report, I beg leave to question. He has evidently to learn, with others, the importance in hospital administration to remember "there is that spendeth and yet increaseth."

In endeavouring to secure a thorough and impartial inquiry in the best interests of the future of Cumberland Infirmary I am handicapped by the apparent general apathy, due possibly to the absence of a local daily newspaper. Mr. Lediard inferentially implies that I have attacked the committee of management, and have found something wrong with the matron, Miss Sylvia Parker. So far from attacking the committee, I have merely urged them to make certain changes in the internal management, and to take steps to secure an independent report by a hospital expert of wide experience. Miss Sylvia Parker has had a most difficult task, and has shown much devotion in her efforts to secure good management under conditions which I venture to think ought never to have existed. They, too, should have been removed before she entered upon her office.

For the rest I commend the present administrative working of the Cumberland Infirmary to the attention of the governors and the committee of management, with the expression of an earnest hope that they will adopt the course recommended in my report, because it should result in increasing the infirmary's resources and bringing its administration in future nearer to the standard of a modern up-to-date hospital.

I am, Sir, yours faithfully,
HENRY C. BURDETT.

Porchester-square, W., Oct. 10th, 1914.

To the Editor of THE LANCET.

SIR,—Sir Henry Burdett seems to have been invited by the chairman of committee and by an eminent member of the honorary medical staff to visit and report on the condition of the Cumberland Infirmary in the year 1909. I raise no objection to this desire for an outside opinion, but some astonishment must have been occasioned when Sir Henry Burdett, like Balaam, does exactly the opposite of what was expected of him: "I called thee to curse mine enemies, and behold, thou hast altogether blessed them these three times." No doubt Sir Henry Burdett's report of the unsatisfactory state of the Cumberland Infirmary has been somewhat disappointing to whoever gave him the invitation.

"It remains to be seen whether the committee and governors of the Cumberland Infirmary will unite to make the administration of the infirmary up to date and smartly efficient," says Sir Henry Burdett on Oct. 10th in the *Hospital*, and so it would seem that the administration is the real point of attack after all, and why does not Sir Henry Burdett leave innuendoes and boldly state what he believes to be wrong? He now tries to whitewash the committee of management and declares that the matron, Miss Sylvia Parker, is worthy of his approval, but what is the "internal management" which "ought never to have existed" and "should have been removed before she entered upon her office"?

I never heard that Miss Sylvia Parker had been hampered by any "internal management"; in fact, I can assure Sir Henry Burdett that there is more harmony and less friction in the Cumberland Infirmary since Miss Sylvia Parker became matron three years ago than there had been for many years previously. Who is the individual aimed at who has "got the affairs of this institution too much into his own hands?" asks Sir Henry Burdett, and I ask Sir Henry Burdett to be frank and say whether or no he does or does not attack the secretary. I can assure Sir Henry Burdett that he has been misled and that the secretary enjoys the full confidence of the committee and has in no way "got the affairs of the institution too much into his own hands." I think that Sir Henry Burdett, if he is attacking the secretary, is sailing a bit near the wind for his own safety, and it appears with absolute clearness that his remarks are resting upon information supplied to him by someone who has an axe to grind.

For his second report in the *Hospital*, Oct. 10th, Sir Henry Burdett remarks: "There is evidence that Dr. Lediard and the infirmary authorities do not appreciate the responsibility of providing adequate recreation-room accommodation for the large staff of laundrymaids they employ." I desire, without any boast, to point out that I raised the question of the need of placing the kitchen and wardmaids above ground instead of their subterranean sleeping-rooms when there was a discussion at the Carlisle Town Hall over the building scheme then in prospect, and I am no less interested in provision being made for our four laundrymaids. Sir Henry Burdett's idea of a large staff of laundrymaids seems to amount to four persons. I have inspected the room the four laundrymaids have for a sitting-room and find it small but adequate so long as it is not invaded by any more.

Sir Henry Burdett objects to my considering the Cumberland Infirmary a "small provincial hospital," and in his report of Sept. 19th he credits us with having 150 beds, but in his Oct. 10th report he drops down to 140 beds, and even then he is in error. There are 100 beds in the hospital in use and have been in use since 1875, but the extensions and ward building recently completed was planned for 130 beds. In spite of the show we have made there are 30 beds still vacant because we have insufficient funds to allow of their being occupied except in an emergency, and these vacant 30 beds have been offered for wounded or sick men from the front by the Red Cross people to the War Office. No one "in the know" can complain that there has been any marked economy in the construction of the new building recently erected, for the palatial dining-room for nurses, the library and vast drawing-room, to say nothing of a large glass-roofed conservatory—all reminding one of a modern hotel—to be found in the nurses' quarters, indicated that expenditure has been lavish; at any rate, it has been so in my opinion.

With regard to Sir Henry Burdett's statement that "a new clinical room to each ward" had been provided, I acquit him of the error, because it was supplied to him on the plan sent to him from the infirmary, but had he been as familiar with the working of a provincial hospital as he would have us believe, he would have recognised the absurdity of a "clinical room to each ward."

There is one passage in Sir Henry Burdett's reply of Oct. 10th which is beyond my comprehension. He says: "I am handicapped by the apparent general apathy, due possibly to the absence of a local daily newspaper." How can the presence or absence of a local daily newspaper influence the "apparent general apathy"? Probably a well-conducted local daily newspaper is an advantage everywhere, but even newspaper proprietors, like hospital managers, are subject to funds for carrying on their business, and if the apathy in the Cumberland Infirmary is to depend "possibly on the absence of a local daily newspaper," I fear we shall be apathetic for many years to come.

Sir Henry Burdett's standard of a modern up-to-date hospital is quite a pleasing one, and includes a series of articles which he considers we now want. Flock pillows are bad, books with readable type needed, a view room in the mortuary, teak floors disappointing, central fireplaces consuming too much coal, &c. These items are not worthy of controversy, but they show how much detail came under Sir Henry Burdett's eye. Does Sir Henry Burdett know that teak is a wood obtained from Burma and has a superior resistance to insect life? Did Sir Henry Burdett actually see the two stoves at work which he complains of as being cheerless and affording insufficient heat? As to a "view room" in the mortuary, which place he thinks has been "erected on a defective plan," what is a "view room"? Perhaps Sir Henry Burdett will instruct me.

If left to himself I feel sure that Sir Henry Burdett means well and is sincere in his desire for improvement in the Cumberland Infirmary, but when he begins to talk about "something wrong somewhere," "little or no spirit or life in the place," "diminished efficiency," and the like hasty deductions, a doubt arises as to his whole report of Sept. 19th. I grant that I have much to learn and will gladly learn from Sir Henry Burdett, but he must write in a different spirit, and report trustworthily, before I can sit at his feet and gather information of the royal road to hospital management, and when he makes himself the mouthpiece of what he has picked up outside the Cumberland Infirmary he damages any reputation he may have for accuracy and good judgment.

I am, Sir, yours faithfully,

Carlisle, Oct. 12th, 191 . H. A. LEDIARD.

⁂ Mr. Lediard's letter is written in answer to a statement in the *Hospital* of Oct. 10th, which is substantially reproduced in Sir Henry Burdett's letter above.—ED. L.

THE DRUG STROPHANTHUS AND THE NEW PHARMACOPŒIA.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 10th, p. 901, attention was called to the alterations in strength of various important preparations, including tincture of strophanthus, in the new Pharmacopœia. The change in this preparation is, however, so drastic, and may have such far-reaching effect, that I feel it requires more extended comment. Strophanthus has been well-known as a powerful remedy in heart affections ever since its introduction into European medicine by Professor Sir T. R. Fraser, and because of its potency it has long been desired that some method of assay and standardisation should be evolved.

Hitherto, however, chemists have been unable to formulate any satisfactory process of evaluation, based on chemical constituents, and recourse has been perforce made to pharmacological tests in physiological laboratories. These were first prominently formulated in a paper read before the British Pharmaceutical Conference at Brighton by Dr. W. E. Dixon in 1905, and the standard set up by him was that "a quarter of a minim of the tincture of strophanthus of the 1898 Pharmacopœia, which has a strength of 1 part of the drug in 40, should be sufficient to arrest the heart in systole of a frog weighing 20 grammes in about one hour." Dr. Dixon expressed the opinion that to meet this standard the tincture of the 1898 Pharmacopœia would have to be diluted, although it was only (approximately) half the strength prescribed in the 1890 Additions to the 1885 Pharmacopœia. Records of experiments spread over some years past, which I have before me, confirm this view, as a clear majority of a number of samples made in accordance with the Pharmacopœia have shown nearly double the potency specified by Dr. Dixon as the desirable standard when tested pharmacologically on frogs. It was, therefore, highly desirable that, when an opportunity of revision occurred, the strength of the tincture should be reduced; but, on the contrary, the Pharmacopœia Committee of the General Medical Council, following the provisions of the international agreement which was signed at Brussels on Nov. 29th, 1906, and which appears to have been based on a slavish adherence to the decimal system rather than on any therapeutic considerations or clinical experience, has increased the strength of the tincture four-fold, making it now 1 in 10 instead of 1 in 40, which, as is shown above, already erred on the side of excessive potency. It is true that at the same time the official dose has been reduced from 5 to 15 minims to 2 to 5 minims, but, as was pointed out last week, the pharmacopœial doses are not in any way binding.

As regards the legal position, it is now well established that the Pharmacopœia is a presumptive standard of strength for all preparations named therein. On and after Dec. 31st next it will be incumbent on all pharmacists to dispense, when tincture of strophanthus is prescribed, the preparation of the new Pharmacopœia, which will doubtless be in many cases four times as powerful and toxic as the writer of the prescription intended.

A very anomalous position will thus be created, involving, not only the throwing of an unfair burden of responsibility upon pharmacists, but also endangering the health and it may be the lives of patients. Although the Pharmacopœia has, I understand, been passed for the press the editors have expressed a desire to be informed of any typographical or other errors which may be discovered by those who have been favoured with a view of advance copies, and it is with the hope that it may not be too late to correct what would seem to be a grave error of judgment that I write this note.

I am, Sir, yours faithfully,
H. WIPPELL GADD, F.C.S.,
Barrister-at-Law; Author of "A Synopsis of the British Pharmacopœia," &c.
Exeter, Oct. 10th, 1914.

CHANGES INDUCED IN BLOOD BY FEEDING.

To the Editor of THE LANCET.

SIR,—My attention having been drawn to the article on sanatogen in the *Journal of the American Medical Association* of Sept. 26th, 1914, p. 1127, I wish to point out that in the paper by Dr. Gage and myself in THE LANCET of Oct. 19th, 1912, the essential point was that the nuclei of nucleated blood corpuscles behave in the same way as do the nuclei of insectivorous plants and also the nuclei of the most diverse other tissue constituents when they are fed on proteins. It is very gratifying that so eminent a physiologist as Professor Carlson should have completely confirmed these changes in the nuclei, although he is unwilling to adopt as yet our explanation. It is regrettable, however, that Professor Carlson should have overlooked the following sentence in our original paper: "Since previous experiments have shown that nuclear changes are produced under normal conditions only by the protein foods and not carbohydrates and fats, we decided on choosing a very concentrated purin-free protein such as caseinogen." If Professor Carlson had not overlooked this sentence it would not have come as a surprise to him that feeding with "sanatogen, milk, crackers, casein, and casein and sodium glycerophosphate" produces the same result. Here again is a complete confirmation of our work, as all these preparations, including the crackers, contain protein. In conclusion, we want to reiterate the statement that we still hold milk proteins free from fat and sugar to be the ideal food for mammals whenever quick recuperation is called for.

The attack on your valuable paper is so scurrilous as to need no comment.

I am, Sir, yours faithfully,
GUSTAV MANN,
Professor of Physiology.
Tulane University of Louisiana, New Orleans, La.,
Sept. 28th, 1914.

PEDICULOSIS OF THE SCALP AND EYE DISEASE.

To the Editor of THE LANCET.

SIR,—May I call attention through your columns to an important, but I believe not sufficiently recognised, point in combating a form of eye disease which is exceedingly prevalent amongst children of the Board School class? I refer to the so-called phlyctenular keratitis, a disease which is responsible not only for much immediate suffering, but also for the most deplorable sequelæ in the form of visual disabilities resulting from corneal scars.

Methodical examination has convinced me that in the majority of the more severe examples of this condition the factor primarily responsible is a pediculosis of the scalp, the ocular affection owing its origin to a transference, in all probability by the fingers, of infective material from the scalp to the eyes. Nobody who has investigated the point in a series of cases can fail to recognise the intimate relationship between these two affections, or to be impressed time after time on the one hand by the beneficial effect upon the eye condition of treatment directed to the scalp, and on the other hand by the inadequacy of such ocular treatment as does not take cognizance of this relationship.

These considerations, apart from any others, appear to me to afford an urgent indication for the frequent periodical examination of the heads of all school children, followed when necessary by appropriate treatment, and facilitated by a regulation that, in the case of boys at any rate, the hair must be kept cropped close to the scalp. I am convinced that such a procedure would obviate much suffering and severe injury to sight, and would thus be justified not only on humanitarian but also on economical grounds.

I am, Sir, yours faithfully,
Oct. 6th, 1914. A. C. HUDSON.

ALPINE TREATMENT FOR THE COMING WINTER.

To the Editor of THE LANCET.

SIR,—I should be glad of the hospitality of your columns to correct a widespread impression amongst the medical profession in Great Britain that the Alps are not available during the coming winter as a health resort for British subjects. As far as this town is concerned the conditions have scarcely been changed at all by the war. The various hotels and pensions are with slight exception open and charging their usual prices. The local authority is prepared to guarantee that there will be no shortage of food supplies or of fuel, and the deficiency of horses due to the mobilisation has been rendered of no importance by the opening of the electric railway from Coire. Arosa has long been the Alpine resort in Switzerland with the largest proportion of English visitors, thus ensuring the safeguarding of their interests at a time when national feeling runs strong. There is perhaps a special reason that British visitors whose health makes it desirable for them to spend the winter here should make a point of doing so this winter in order that the pleasant traditions of the British colony may not be lost for future years.

The journey should not constitute a difficulty, even assuming that the usual route remains unavailable. Messrs. Thomas Cook and Sons in London have the matter in hand and are prepared to advise as to what route is available at a particular time. There is now a regular service of boats to Bordeaux, whence the journey to Geneva lies quite outside the zone of warfare; or France may be avoided altogether by the sea route to Genoa and thence by Milan and the St. Gothard.

I am, Sir, yours faithfully,
Arosa, Switzerland, Oct. 1st, 1914. EGBERT MORLAND.

IONISATION FOR BILHARZIASIS.

To the Editor of THE LANCET.

SIR,—As the condition of vesical and rectal bilharziasis is so intractable and virtually unaffected by any generally practised treatment, anything promising relief from this troublesome condition is to be welcomed. Owing to the embedded situation of the parasite and consequent difficulty of penetration of efficacious therapeutic agents that will not by reason of their potency at the same time prove harmful to the mucous membranes, it is not surprising that here, as in the somewhat analogous case of ringworm, the results of ordinary treatment are so hopelessly disappointing. By the modern device of causing chemical penetration through the agency of the constant current I would suggest that a valuable and satisfactory means may hereby present itself for dealing with bilharzial infections by means of ionisation, and I think this procedure might be given a fair and extended trial in this condition. The ionising fluid having been introduced into the bladder or rectum and a suitably insulated electrode inserted, the ordinary technique is employed. The results of ionisation for ringworm are also likely to improve so much with the advance of technique as to cause this method ultimately to supplant all others.

I am, Sir, yours faithfully,

G. S. THOMPSON, F.R.C.S. Eng.

Kimberley, South Africa, Sept. 12th, 1914.

OSTEO-ARTHRITIS OF THE HIP-JOINT.

To the Editor of THE LANCET.

SIR,—I am very unwilling to trouble you further on the personal matter of the views I have expressed as to the connexion between the term "sciatica" as ordinarily understood and osteo-arthritis of the hip-joint. In my "study" of the disease a reference to the appendix will show that in my experience the vast majority of the cases there detailed proved the presence of "trouble" in the hip-joint. Given such trouble of a gouty nature I further ventured to suggest that in certain neglected individuals the result was an osteo-arthritis. Dr. Jones and Dr. Llewellyn have found in another set of cases trouble in the joint associated with pain along the anterior crural and obturator nerves. I have again to say their observations constitute a strong and additional reason for the careful examination of the articulation.

I am, Sir, yours faithfully,

Dingwall, Oct. 6th, 1914. WILLIAM BRUCE.

To the Editor of THE LANCET.

SIR,—The recent paper on osteo-arthritis of the hip by Dr. R. Ll. J. Llewellyn and Dr. A. Bassett Jones and the resulting correspondence deal with some extremely important and debatable problems. Few will agree with Dr. W. Bruce's view that sciatica is practically always due to osteo-arthritic changes in the hip-joint. Personally in examining a patient with definite sciatic pain the hip-joint is not uppermost in my mind, although as a routine this joint is examined. There are many far more common causes of sciatica than the above-mentioned lesion. Primary sciatica I believe to be extremely rare. Dr. Llewellyn and Dr. Bassett Jones, on the contrary, hold that gouty sciatica is a common primary form. In most cases sciatic pain occurring in individuals with definite gouty lesions, or with vague manifestions of the gouty diathesis, can be explained on static grounds. True sciatic neuritis dependent on microbic infection such as the streptococcus rheumaticus is occasionally seen and can be correctly designated as primary sciatica. The bulk of the cases, however, are secondary in origin, lesions of the spine, spinal cord and meninges, pelvic viscera, and static defects accounting for the majority.

Lesions of the sacro-iliac joint are well recognised as competent causes of sciatic pain, but there is still a great deal of confusion as to the exact type of lesion present. In this controversial subject I have taken a great deal of interest, as during last winter I had a unique opportunity of investigating a series of such cases in the Orthopædic Clinic of the Massachusetts General Hospital, Boston, a clinic which is the home of sacro-iliac affections. Since the original paper of Goldthwait and Osgood in 1905, cases presenting certain features have been indiscriminately called sacro-iliac relaxation, strain, or displacement. Dr. Llewellyn and Dr. Bassett Jones evidently recognise the existence of relaxation of the sacro-iliac joints. In a communication in the *Boston Medical and Surgical Journal* of June 25th, 1914, and in another paper shortly to be published in the *Medical Chronicle* I have discussed the evidence for and against sacro-iliac relaxation as an entity.

Professor Lovett, of Boston, has recently considered this question, and has expressed views contrary to those generally accepted. Briefly the position at present is as follows. Of cases manifesting the sacro-iliac syndrome, of which lumbago and sciatica are prominent features, a certain proportion are due to traumatic strain of the sacro-iliac joint, a condition seen most frequently in the male sex. The remaining cases in which injury has played no part are to be classed as static postural defects, or what Lovett calls defective balance. In all of these an obvious bad body poise is present with a shifting forward of the centre of gravity of the body. Excessive strain is thrown on to the posterior musculature of the spine and lower limbs, a strain which manifests itself in pain and tenderness at ligamentous insertions; that is lumbago and sciatica. The direct treatment of the postural defect relieves the sciatica. There can be no doubt that sacro-iliac relaxations are practically non-existent; in the male sex such a condition is an anatomical impossibility. I feel sure that gouty sciatica is static in origin in the majority of instances. Osteo-arthritis of the lumbar spine is a not infrequent cause of sciatic pain, unilateral or bilateral; this lesion accounts for a considerable proportion of cases of so-called sciatic scoliosis. Amongst the many other causes of secondary sciatica spinal cord tumours and chronic spinal meningitis are noteworthy, as they are usually diagnosed late. The possibility of these two lesions should always be borne in mind.

In conclusion, there is one other point in Dr. Llewellyn and Dr. Bassett Jones's paper which invites discussion. The authors state that in the later stages of osteo-arthritis of the hip-joint treatment is of little avail. This is hardly in keeping with modern surgical advances. There are two procedures which give excellent results in selected cases—(1) the operation cheilotomy, and (2) arthrodesis. The former operation is satisfactory in cases where the osteophytes are responsible for most of the pain and crippling. Arthrodesis is particularly indicated in a younger individual in whom a painless stable joint will enable the patient to continue his occupation. The technique devised by Albee, of New York, is generally followed, the limb being fixed in full abduction until bony union is attained.

I am, Sir, yours faithfully,

HARRY PLATT, M.S. Lond., F.R.C.S. Eng.

Manchester, Sept. 28th, 1914.

THUCYDIDES ON THE PLAGUE AT ATHENS.

To the Editor of The Lancet.

Sir,—In your review of Dr. Raymond Crawfurd's book "Plague and Pestilence in Literature and Art" in The Lancet of July 4th I note with interest that he holds the view that the disease described by Thucydides[1] as "plague" was really typhus fever. I think that a few extracts from the Greek historian's lurid description should be sufficient to prove the soundness of Dr. Crawfurd's conclusion.

It matters little whether so obscure an individual as myself agrees with or differs from so eminent a classical scholar as Dr. Crawfurd, but it may interest him to know that even in isolated spots in South Africa may be found some who appreciate his services to the historical side of medicine. I came to the conclusion many years ago that the disease described by Thucydides was really typhus fever; but I refrained from raising the question in your columns—though I often thought of doing so—for the simple reason that, remote as I am, and have been for many years, from good libraries, it might have seemed presumptuous on my part to offer an opinion one way or other on a subject which I assumed had been decided by scholars long ago. It should seem, however, from your review that this is not the case; and it is certainly matter for astonishment to me that any medical reader of Thucydides should be in doubt as to the nature of the disease he describes under the name of "plague." As a record of disease emanating from remote antiquity, and written by one who suffered from it himself—"the greatest historian that ever lived," as Macaulay styles him—it must always possess an abiding interest, at least for those to whom the large memories of the Hellenic past make any appeal. Nor will the interpretations of modern science—beyond changing the name of the disease—do particular violence to the historian's reputation for accuracy as to statements of fact. In setting forth my reasons for supporting Dr. Crawfurd's view I may also state the circumstances under which this subject first aroused my special interest.

Some 13 years ago, whilst attached to the South African Field Force, I often found myself compelled to extract what comfort I could from a very limited library. Amongst my books was a copy of Thucydides. The monotony of veld life forced me into communion with this ancient friend, as "something craggy to break my mind against"—to use Byron's metaphor.

I need not pretend that I found the text which alienated Porson, perplexed Arnold, and evoked Macaulay's admiring despair, a source of unmingled happiness. Too often I had to leave the great Athenian alone with his peculiar glory of self-repression and obscurity of phrase. Enough, however, remained to come within the scope of my powers, and of that the description of the plague at Athens claimed my particular attention. In an article written by me then and published in your columns[2] I made a passing reference to the subject, but there I left it, as it was foreign to the matter under discussion.

Now, taking a few of the symptoms of typhus fever as described in a modern text-book of medicine—such as, for instance, pyrexia, headache, injected conjunctivæ, vomiting, bronchial catarrh, thirst, mottled rash, and sleeplessness—let us see what is to be found in Thucydides about each and all of them. It will, in fact, be seen that each of these symptoms is discussed by him almost in the order in which I have given them: 1. "Violent heats in the head." (*"τῆς κεφαλῆς θέρμαι ἰσχυραὶ."*) 2. "Redness and inflammation of the eyes." (*"τῶν οφθαλμῶν ἐρυθηματα καὶ φλόγωσις."*) 3. "Sneezing and hoarseness came on, and in a short time the pain descended into the chest with a violent cough." (*"πταρμος καὶ βράγχος ἐπιγίγνετο ἐς τά στήθη ὁ πόνος μετα βηχὸς ἰσχυροῦ."*) 4. Vomiting (*"καὶ ὁπὸτε ἐς τὴν καρδίαν στηρίξειεν ἀνέστρεφέ τε αυτὴν"*)—i.e., "when it settled in the stomach, it upset it." 5. A rash of a "reddish" (*ὑπὲρυθρον*) "livid" tint (*πελιτνον*). 6. Thirst. This was so great that not even the lightest clothing could be borne. The stricken ones lay stark naked, and many threw themselves into the cisterns, "being in the grasp of an unquenchable thirst" (*"τῃ διψῃ ἀπαυστῳ ξυνεχομενοι"*). 7. Sleeplessness (*"καὶ ἡ ἀπορία μὴ ἡσυχαζειν καὶ ἡ ἀγρυπνία ἐπέικετο δια παντός"*)—i-e., "and the misery of restlessness and wakefulness weighed upon all." This is a fairly good description of the "coma-vigil" of modern clinicians. The other symptoms described correspond to our sequelæ. They are: gangrene of the genitalia, fingers, and toes, loss of eyes, and sometimes complete loss of memory (probably dementia):—*"κατεσκηπτε γὰρ ἐς ἀιδοια καὶ ἐς ἀκρας χειρας καὶ πόδας,"* &c. …… *"τους δὲ καὶ λήθη ἐλαμβανε,"* &c.

So far, then, and no farther does it seem to me necessary to quote from Thucydides to establish the view that he is in reality describing typhus fever.

I am, Sir, yours faithfully,

Duncan Mackenzie Macrae, M.A., M.B.,
Ch.B. Glasg.

Roberts Victor Diamond Mine, Victor, O.F.S., Sept. 1st, 1914.

[1] Hist., Bk. 2, chaps. 47–53.

[2] The Lancet, June 27th, 1908, p. 1838.

Central Midwives Board.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Oct. 8th, with Sir Francis H. Champneys in the chair. A letter was considered from Miss Llewellyn Davies, general secretary of the Women's Coöperative Guild, asking the Board to appoint a representative to join a deputation to the President of the Local Government Board, in his capacity as such and as chairman of the Government Committee for the Relief of Distress, to consider the care of maternity in time of war. The Board directed that Miss Llewellyn Davies be informed that the Central Midwives Board, while sympathising with any scheme which had for its object the care of maternity in time of war, did not see its way to join the deputation. A letter was considered from the secretary of the County Councils Association transmitting a copy of a resolution passed by the executive council at its meeting on July 29th with regard to the registration and inspection of lying-in homes, institutions, and houses where women are habitually taken in for their confinement for pay. The secretary to the Board reported that the executive council of the County Councils Association had resolved that in the opinion of the council it is desirable that all lying-in homes should be registered and inspected by the inspectors of the local supervising authorities under the Midwives Act. Further correspondence was considered with regard to a complaint made by a certified midwife of the conditions of midwifery practice in Bangor and the absence of inspection by the local supervising authority. The Board decided that the correspondence be referred to the County Councils Association. A letter was considered from a certified midwife approved by the Board for the purpose of undertaking the practical training of pupils at her nursing home, asking that her approval may be extended to cover a second training home not in the immediate vicinity of the first. The Board decided that the application be refused.

THE WAR.

ARMY MEDICAL SERVICE: A SPECIAL SANITARY COMMITTEE.

THE Director-General of the Army Medical Service reports a highly satisfactory state of health of the armies camped, billeted, or quartered in the various commands at home. Nowhere is there any undue prevalence of preventable disease, and the massing of large numbers of men in the military and other stations under difficult conditions has not been accompanied by any untoward results.

Concerning the health of the Expeditionary Force, the Director-General reports an equally satisfactory state of affairs. He is satisfied that the utmost vigilance is being exerted to maintain the present position. To ensure still greater security Lord Kitchener has decided to establish at the War Office a sanitary committee, consisting of military and civilian members, to advise him on all matters affecting the health and well-being of troops at home and abroad. He is also sending the Director-General, Sir Arthur Sloggett, overseas to make a thorough inspection of the medical arrangements and coördinate the work of the Army Medical Services with the St. John Ambulance and Red Cross Societies, of which he will be Chief Commissioner. Sir Arthur Sloggett will be accompanied by Colonel Burtchaell, Royal Army Medical Corps, as staff officer. During his absence at the seat of war Sir Alfred Keogh will act as Director-General at the War Office.

NEW CONSULTING PHYSICIANS WITH THE EXPEDITIONARY FORCE.

Sir Almroth Wright, Sir Wilmot Herringham, and Sir John Rose Bradford have been appointed consulting physicians with the Expeditionary Force.

FREE MEDICAL ATTENDANCE FOR THE DEPENDENTS OF MEN ON ACTIVE SERVICE.

In our issue of Sept. 19th we published a letter from Mr. J. A. Pease, President of the Board of Education, announcing that a scheme had been devised for providing medical attendance, with medicine and appliances, to necessitous dependents of soldiers and sailors serving with the colours. The Central Committee for the Prevention and Relief of Distress set up a special subcommittee to bring this scheme into operation on a properly organised and comprehensive basis. A circular issued this week by the subcommittee, which is now known officially as the Naval and Military Dependents (Medical Treatment) Committee, announces that the necessary arrangements having been made, the British Medical Association and the Pharmaceutical Society have communicated with individual members of the medical and pharmaceutical professions, informing them of the detailed arrangements adopted and inviting their coöperation. To this appeal a generous response has been received from medical men and chemists in all parts of the country, who have intimated their willingness to give their services in accordance with the scheme, and the cordial coöperation of Local Representative Committees is invited. These committees are asked to arrange for the distribution of medical vouchers to dependents in need of medical treatment in accordance with the offers of service made by medical practitioners and pharmacists. This voucher, which is called the Medical Book, and of which we have received a specimen copy, will enable the recipient to obtain free medical treatment, and contains prescription forms which will secure free drugs and appliances, the latter according to a fixed schedule, from the chemist. These vouchers will, of course, not be issued to persons entitled to medical benefit under the National Insurance Act, and it will be open to medical men or chemists to make representation to the Local Representative Committees, where it would appear that the circumstances of persons applying for assistance do not entitle them to be admitted to the benefits of the scheme. Applications for copies of the above circular, for supplies of the medical book, or for information on other matters should be made to the joint secretaries, Naval and Military Dependents (Medical Treatment) Committee, Wellington House, Buckingham Gate, London, S.W. Briefly summarised, the duties of the Local Representative Committees in connexion with this scheme are (*a*) to arrange for the issue of medical books to suitable recipients, and (*b*) to keep a list of persons to whom books have been issued.

THE CONDITION OF OUR WOUNDED.

A surgeon on service at one of the London base hospitals (Territorials) has given us some impression of the wounded who have come under his care which will relieve certain widely spread apprehensions. Of those who came from the front after the battle of Mons and during the retreat the majority suffered from general exhaustion, want of rest, and foot-soreness rather than from wounds, and rest and care worked immediate restoration in the majority of cases. Of those who came after the battles of the Marne and the Aisne, nearly all were suffering from shell and bullet wounds, the number of the former greatly preponderating, this observation thus exactly bearing out Mr. Makins's statement of the position in the French hospitals. The striking point, said our informant, was the extraordinarily good condition in which the men arrived and the careful and cleanly nature of the dressings. Considerably less than 10 per cent. of any suppurating wounds came under his notice, which is gratifying information taken in connexion with the comparatively large proportion of shrapnel injuries. Rapid healing has taken place in many cases and the men soon regained their general health. On inquiry from them it became evident that every possible opportunity had been taken during their transport to change the dressings, and the commissariat arrangements appear to have been admirable, the men expressing themselves as having been well fed all through their long journey of several days. In fact, the cheerfulness of those who have been returned from the battle of the Marne, despite their wounds, was in marked contrast to the depressing condition of those who had taken part in the retreat from Mons. This first-hand evidence of good organisation and thorough attention will be received with much pleasure.

THE FRENCH MEDICAL PROFESSION AND THE WAR.

To those who are accustomed to receive regularly the medical journals of the continental nations now at war their abrupt cessation with the outbreak of hostilities brings with it a curious sense of isolation. Whether the German medical weeklies are being printed we actually do not know, but correspondents in Switzerland indicate that some at least are still appearing. A letter from Paris, published in the *Journal of the American Medical Association* for Sept. 19th, states that the *Semaine Médicale* has ceased publication and that the *Presse Médicale* is appearing as a sheet of medico-military information. The writer of this letter gives some interesting particulars of the way in which the profession in France, as in Britain and Germany, has volunteered its services to the army and the navy. As in these other countries, too, certain districts have been seriously depleted of medical practitioners, but steps have been taken to see that the really sick are not without such professional service as they may need. The French Red Cross Societies are three in number: the Société de Secours aux Blessés, the Association des Dames Françaises, and the Union des Femmes de France. These societies between them are able to provide their country with 600 hospitals containing 35,000 beds and a staff ready to act, while the Union des Femmes de France can send 10,000 trained nurses to the army. The Académie de Médecine has undertaken the manufacture of small-pox vaccine, and a general campaign of vaccination and revaccination has been organised. It is also advising general antityphoid vaccination, not only for the army, where it is compulsory, but also for the civil population. The Académie des Sciences has appointed committees to deal with various subjects, including hygiene and medicine. The sale of absinthe has been forbidden throughout France. The war is at the present time demanding a much larger proportion of the available energies in France and in Germany than it is in this country, and it behoves Britain to see to it that when her own resources are more heavily taxed, as they certainly will be later on, everything and everybody is ready for service.

MEDICAL CASUALTIES AT THE FRONT.

The following additional announcements have been made with regard to officers of the Royal Army Medical Corps at the seat of war:—

Missing: Lieutenant R. A. Flood.

Captain G. A. Kempthorne, previously reported missing, is now unofficially reported wounded and a prisoner of war; Colonel H. N. Thompson, Major H. W. Long, Captain J. H. Graham, Captain G. H. Stevenson, Captain E. S. B. Hamilton, Captain H. B. Kelly, and Captain R. J. Cahill, previously reported missing, are now unofficially reported prisoners of war.

The first list received from Germany of British officers who are prisoners of war contained the following medical names: Major P. H. Collingwood, Major W. B. Fry, Major J. C. Furness, Captain W. K. Beaman, Captain J. P. Lynch, Captain E. M. Middleton, Captain A. A. Sutcliff, Lieutenant A. T. Brown, Lieutenant P. P. Butler, Lieutenant S. M. Hattersley, Lieutenant H. W. Hills, Lieutenant J. L. Lauder, Lieutenant A. Preston, and Lieutenant L. M. Routh.

In the list of wounded British officers in Paris hospitals furnished to the press by Lord Robert Cecil appeared the names of Major E. McDonnell, R.A.M.C. (at Versailles), and Lieutenant A. Watson, R.A.M.C. (at Claridge's).

OBITUARY OF THE WAR.

CHARLES DALTON, L.R.C.P. & S.IREL.,

LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Charles Dalton, who died of wounds received in action, was born on May 3rd, 1867. He was educated at Carmichael College, Dublin, and obtained the diplomas of the Irish Royal Colleges in 1888. He joined the Army Medical Service as surgeon in January, 1891, became Major in the Royal Army Medical Corps in January, 1903, and was promoted Lieutenant-Colonel in May of last year. Before the outbreak of war he was stationed at Dublin, holding the post of deputy assistant director of medical services. Colonel Dalton had a long and distinguished list of war services. He served in Burma in 1893, being present at operations in the Kachin Hills, for which he received a medal with clasp. In 1897–8 he served in the North-West Frontier of India, taking part in the Malakand expedition and the action at Landakai, receiving a medal with clasp. In 1898–9 he took part in the Karene expedition in Sierra Leone, and was mentioned in despatches and received a medal with clasp. In the following year he served in the South African war as a special service officer, taking part in operations in Natal and being present at the relief of Ladysmith, where he was severely wounded. He was also engaged in operations in the Orange Free State during 1900, including actions at Houtnek, Vet River, and Zand River; and in Cape Colony, south of Orange River. He was mentioned in despatches, and received the Queen's medal with three clasps.

FRANK FORREST, M.R.C.S. ENG., L.R.C.P. LOND.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain Frank Forrest, who was killed in action on or about Sept. 13th at the battle of the Aisne, entered Owens College, Manchester, as a medical student in the session 1895–96, living at that time with his mother at Blackburn. After pursuing the usual course of studies for the English Conjoint diplomas he qualified M.R.C.S. Eng. and L.R.C.P. Lond. in 1904. After qualification he held the post of assistant house surgeon in the North Staffordshire Royal Infirmary, Stoke-on-Trent. He joined the Royal Army Medical Corps as lieutenant in January, 1906, and was promoted captain in July, 1909. Before the outbreak of war Captain Forrest was stationed at the Royal Army Medical College, and was then attached to the Irish Command.

HUGH JAMES HOPPS, M.B., CH.B. EDIN.,

SURGEON, ROYAL NAVY.

Surgeon Hugh James Hopps, who was drowned when H.M.S. *Aboukir* sank on Sept. 22nd, was born at Chipping Norton, Oxfordshire, in 1887. He studied medicine at Edinburgh, and graduated M.B., Ch.B. at the University in 1911, after a creditable career as a student. He was a popular member of the Edinburgh Students' Union, and held a prominent position among the men of his year. He entered the navy as surgeon in October, 1913, and joined the ill-fated *Aboukir* at the beginning of August.

ALFRED EDWARD TURNBULL, M.B., CH.B. EDIN.,

SURGEON, ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Alfred Edward Turnbull, who went down with H.M.S. *Cressy* on Sept. 22nd, was born at Pinkerton, Dunbar, on March 10th, 1882, the son of Mr. Phipps Turnbull, of Edinburgh.

He studied medicine at Edinburgh University, the Royal College of Surgeons of Edinburgh, and Glasgow University. He graduated M.B., Ch.B. at Edinburgh in 1907, and was clinical assistant in the University surgical wards of the Royal Infirmary, Edinburgh, in 1908, resident house surgeon in 1908–09, and resident gynæcologist in 1909–10 at the Royal Infirmary. Previously he had been Mackenzie bursar in anatomy and prosector in the University of Edinburgh. Dr. Turnbull was in practice at Faringdon, Berkshire, and having been a surgeon in the Royal Naval Volunteer Reserve since January, 1912, he was called up when the Navy was mobilised and joined his ship on August 1st. A popular and able young physician, of whom much was expected in his future career, he was a Fellow of the Edinburgh Obstetrical Society, and had published several communications upon subjects connected with midwifery.

ARTHUR KEITH ARMSTRONG, M.R.C.S. ENG., L.R.C.P. LOND.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant Arthur Keith Armstrong, who died in France on Sept. 15th from wounds received in action, was born in 1881 in London, and was the only son of Mr. Henry Armstrong, of Dartmouth Park-road, London, N.W. He was educated at Highgate School and St. Bartholomew's Hospital, and qualified at the English Conjoint Board in 1907. Soon afterwards he became house surgeon at the Huntingdon County Hospital, and later surgeon on board the British India mail steamship *Jelunga*. In 1909 he entered into partnership at Monmouth with Dr. Lloyd G. Smith and was appointed honorary medical officer to the Monmouth Hospital in the same year. He married Louise, daughter of John Macmin, and leaves two children. When war was declared he offered his services to the War Office, and was gazetted temporary lieutenant in the Royal Army Medical Corps on August 18th. After a short period at Woolwich he was sent abroad to join the Expeditionary Force, and was one of the first medical men to lose his life for his country.

HERBERT LESLIE HOPKINS, M.D., B.S. LOND.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant Herbert Leslie Hopkins, assistant county medical officer of health of West Suffolk, was reported as being killed on Sept. 19th whilst serving with the Expeditionary Force. He had received permission from the county council on August 10th to volunteer for active service, and joined the forces at Devonport on August 15th as bacteriologist and pathologist to the military hospital there. On August 26th he sailed for France. He was born on August 23rd, 1887, and joined Guy's Hospital in 1905, having obtained an entrance scholarship in arts. During his student career he was a student demonstrator in physics, anatomy, microscopic pathology, and bacteriology, and pathological assistant to the surgical registrar. He took the degree of M.B., B.S. of the University of London in November, 1911, at the same time passing the examination for the M.R.C.S. Eng. and L.R.C.P. Lond. After qualification he devoted some time to study in various special departments at his medical school. Subsequently to serving as house physician to the Derbyshire Royal Infirmary in 1912, he was appointed house physician to the City of London Hospital for Diseases of the Chest, which appointment he held until Sept. 1st, 1913, when he commenced his work in West Suffolk. In July of this year he passed the examination for the degree of M.D. in State Medicine in the University of London. Dr. A. H. Bygott, county medical officer of health of West Suffolk, writes: "By the death of Lieutenant Hopkins the medical profession, especially the sanitary branch of it, has lost one of its ablest junior officers. He was a man of high attainments, a sound physician, capable surgeon, and good bacteriologist. During the year he worked with me I formed the highest opinion of his capabilities, and had his life been spared I feel sure there is no position in his profession to which he might not have attained. His kindly disposition and pleasant manners made him a general favourite both in official and social life. Able, energetic, conscientious, and very thorough, his death is a calamity to his colleagues and to the council he so loyally served."

CASES FROM THE FRONT AT THE SECOND EASTERN GENERAL HOSPITAL.—The two fresh convoys of wounded from France admitted to the Second General Eastern Hospital, Brighton, contained many men very seriously injured. The wounds were mostly from shrapnel received at the battles of the Marne and the Aisne. Many of the patients were utterly exhausted on arrival, having been travelling by train and boat under most unfavourable circumstances for seven days. However, with rest and care it is wonderful how well they have pulled round. Of nearly 600 admissions from the war from Sept. 1st to the present there have only been three deaths. Among the casualties there were a large number of bullet wounds of bones and joints, many of them septic and very badly comminuted. Every possible effort is being made to save the limbs, even in the worst cases, and so far there have been no amputations performed. It is almost impossible to hope that none will have to take place, as some of the wounds are extremely bad, but in a great many there is no doubt that the limb will be saved. Appended are notes of a few of these cases.

Compound fracture of the head of the humerus: This was an injury of the upper part of the arm, breaking the head of the humerus. About ten days after the wound the patient had a sudden swelling over the pectoral muscles of considerable extent, and he at the same time became very blanched. It was clear that there was a large subcutaneous hæmorrhage. The swelling was incised and attempts were made to tie the bleeding vessel. This was found to be impossible, and therefore the subclavian artery was ligatured. This procedure stayed the main part of the bleeding, but it was necessary to plug the wound to arrest a good deal of rather free oozing. He did very nicely for a month, when he had after some slight exertion free bleeding from the wound, which was stopped by plugging with gauze. This happened a second time about a week later. He is now in a bad state from loss of blood, and will certainly not be able to stand many more such attacks. *Injury to knee-joint:* In one case the whole knee is disorganised, the upper end of the tibia and the lower end of the femur are smashed, and the joint is full of blood. Although an attempt is being made to save the limb success is very doubtful. A second example of wound of the knee is the following. The bullet was lodged between the patella and the lower end of the femur without any fracture. It was removed, but there is extensive synovitis, happily at present not purulent. There are a few very interesting cases of *bullet wounds of the skull.* In the first case the man was struck by a bullet in the left vertical region, and left lying in a trench half filled with water for 40 hours, with practically no attention. When picked up he was found to have paralysis of the right leg. On admission he had a punctured wound of the vertex, with small pieces of depressed bone. There was no sign of any bullet, although there can be little doubt that it is lodged somewhere in the skull. The paralysis of the leg has quite cleared up. The lesion here was some slight injury to the leg centre in the left cortex. In a second case, the man was struck by a bullet in the vertex, and on his admission there was found a wound on this part into which had been driven deeply several pieces of bone. The brain into which the bone had been forced was suppurating. X ray examination showed no trace of the bullet. The wound was opened up, the skull trephined, the pieces of loose bone removed, and the abscess drained. The question here is, Did the bullet enter the skull and become hidden somewhere in the base, or did it strike tangentially, glance off, and simply drive in the fragments of bone without itself entering the cranium? At any rate, whatever happened the man is now making very good progress. A curious case is one of *concussion of the spine.* The patient had marched and fought for two days practically without food, when he was struck by a piece of shrapnel in the upper part of the left thigh, the bullet passing upwards and lodging under the skin of the right ribs low down. He lay on the ground in pouring rain for 48 hours, all the time exposed to shell fire, without food or water, or assistance of any kind. He found that he was paralysed in both legs, had no sensation in them, and could not empty his bladder. At the end of this time our men drove the Germans back and the ambulance was able to collect the wounded. A surgeon on the field at once passed a catheter, and the bullet was extracted during his journey on the boat to Southampton. He is now rapidly getting well. He has the full use of his legs, sensation is returning, but so far the bladder and rectal paralysis is still present. The rapid improvement of the cord symptoms is clear proof that there was no actual severance of the organ. Probably what has happened is this. The bullet, in passing by the spine, gave rise to a well-known phenomenon of bullet wounds, and caused a rapid vibration of the cord, and thus produced the symptoms of concussion. The prognosis is quite good; already, as mentioned, the symptoms are rapidly clearing up. *Bullet wound of the liver:* This man was shot through the upper part of the abdomen, the bullet passing through the liver. On admission he was passing blood per rectum, and there was a swelling in the abdomen, which was at once opened and found to be an abscess. The bleeding from the rectum stopped. The abscess drained well, and the man did nicely for a month, when he was suddenly seized with symptoms of acute intestinal obstruction—e.g., persistent vomiting, constipation, and pain. His abdomen was opened and it was found that there were many recent adhesions binding down the bowel and causing blocking. These were as far as possible released, but it was found impossible entirely to relieve the obstruction in this way, and therefore the dilated small intestine was joined to the large bowel. The man is now, 48 hours after the operation, somewhat better, but in a very precarious state. *Shrapnel wound of the pelvis:* This man was struck by a shrapnel bullet in the lower part of the abdomen, which passed through his pelvis, just missing the bladder, and finally lodged high up in the thigh. Some considerable difficulty was encountered in removing it, but it was finally found embedded in the femur and taken out. *Shrapnel bullet embedded in the head of the tibia:* The patient was struck in front of the leg, the bullet passing directly backwards and lodging in the head of the tibia just over the popliteal artery. It was causing a good deal of pain, and there was a discharging sinus, so it was decided to take it out. The sinus in the bone was enlarged by chiseling, and the bullet found embedded in the bone, in which there was an abscess cavity, which is now doing well. *Extensive shrapnel wound of the buttock:* This man had half his buttock blown off by shrapnel. There was a large sloughy wound of the buttock, which is healing rapidly with peroxide of hydrogen and iodoform dressings. It is referred to as an example of extensive wound of soft parts causing considerable disablement, for it will be very many weeks before the patient is fit to resume duty. These examples show how serious have been many of the cases sent to the hospital, and how fresh and varied has been the experience of the surgeons attached to the staff.

First Northern General Hospital (T.F.), Newcastle-on-Tyne.—The staff of this hospital is derived from that of the Royal Victoria Infirmary, Newcastle-on-Tyne, and the following is the personnel which has been mobilised:—Commanding Officer: Lieutenant-Colonel T. Gowans. Registrar: Major F. C. Pybus. Quartermaster: Lieutenant T. Gibbs. Lieutenant-Colonels: T. Beattie, W. E. Hume, A. M. Martin, and H. B. Angus. Majors: W. G. Richardson, J. W. Leech, G. G. Turner, R. A. Bolam, W. D. Arnison, and A. Parkin. Captains: G. Hall, T. M. Allison, D. W. Patterson, H. J. Slade, F. G. Armstrong, H. H. Markham, W. Seymour, and W. F. Wilson. Officers not yet mobilised: Major Wardale, Major Lyle, and Captain Whillis. The hospital has its quarters in the Armstrong College, Newcastle-on-Tyne, where class-rooms, &c., have been converted, after making the necessary sanitary additions, into wards. There have been arranged medical and surgical blocks, and also a block for venereal and parasitic diseases, this last entirely separate from the general wards. In addition to the beds thus arranged further accommodation has been secured by taking wards in the Royal Victoria Infirmary, which is adjacent to the college. In all some 650 beds are available, 450 in the college and 200 in the infirmary. The contiguity of the infirmary and college is most convenient, since the major surgical cases can be dealt with in the infirmary; moreover, the radiographic department in the infirmary is thus available. For minor surgical cases, varicose veins, hæmorrhoids, &c., a theatre has been arranged in the art department of the college. The kitchen arrangements are developed from those already existing in the College Refectory. The non-commissioned officers and men have their quarters in the Grand Assembly Rooms, also an adjacent building, while the nurses, about 100 in all, are quartered in the Royal Infirmary and also in the Grand Hotel. The whole block of buildings adapts itself admirably for the purpose of a temporary hospital. The hospital commenced its mobilisation on the evening of August 4th, and the first patient was admitted on the 7th, two days under the scheduled time for mobilisation. The hospital serves as a base and general hospital for the many troops now quartered between Berwick and the Hartlepools, though its proper area of supply includes an even greater portion of the Northern Command. A glance at the figures of patients admitted shows the amount of work which has been done already. During August (from the 7th) 545 cases were admitted, in September 898, and in October (up to the 7th) 216; in all, a total of 1659. In addition to the above figures, 242 men, wounded or sick from the Expeditionary Force, have been treated, a grand total of 1901 patients in two months. As patients convalesce they are returned to their units or sent for further treatment to other quarters which have been adapted to receive them—at Middlesbrough, Darlington, the Workhouse Infirmary (where wards have also been taken), Newcastle, Sunderland Eye Infirmary, and Blagdon Hall, Northumberland, the seat of Lord Ridley. The cases of sickness include pneumonia, septic throats, influenzal colds, and venereal and parasitic troubles, among others. No enteric fever has as yet appeared. The surgical operations done number 283, and include hernia (41), appendicitis (24), loose semilunar cartilage (13), hæmorrhoids (22), ruptured duodenal ulcer (3), varicose veins (18), and compound fractures (31). The staff, non-commissioned officers, men and nurses, have volunteered for service abroad practically unanimously.

War Appointments.—Colonel M. W. Russell, R.A.M.C., and Lieutenant-Colonel Sir H. Thornhill, K.C.I.E., have been appointed Inspectors of Administration, Medical and Sanitary Services, in connexion with the places of internment of prisoners of war.—Lieutenant-Colonel F. Wyville Thomson, I.M.S.(R.), has been appointed Senior Medical Officer, Tay Defences, Dundee.—Major Sir E. S. Worthington, medical officer to the Duke of Connaught, left Ottawa on Oct. 9th for the front.

The 2nd London Sanitary Company.—There are vacancies for two suitable officers in this unit. These two vacancies will be filled by duly qualified medical men, who should hold the D.P.H. or possess a public health degree. They should be willing to join for the period of the war or for four years, and they should be willing to serve abroad. If physically fit they should apply personally at the orderly room of the 2nd London Sanitary Company, R.A.M.C. (T.F.), to the commanding officer at the Duke of York's headquarters, Chelsea, S.W., at 10.15 any morning except Sunday. The work of the company is most interesting and valuable. It includes everything that appertains to the best sanitation of camps—e.g., the construction of incinerators, the control of water-supply and ablution places, the arrangement and control of kitchens, and the disposal of refuse. The experience that will be gained by young men working in this company will stand them in good stead all their lives, and it is not likely that the vacancies, now that they are announced, will remain for an hour without their applicants.

CITY OF LONDON HOSPITAL FOR OFFICERS.—The City branch of the British Red Cross Society, acting in conjunction with the Fishmongers' Company and with the generous help of City firms, has fitted up the first floor of the handsome hall of the company, overlooking the Thames at London Bridge, as a complete hospital for officers wounded in the war. The work of internal reconstruction and equipment has been admirably carried out, and the white-walled cubicles into which the hall has been subdivided have a most cheerful and comfortable appearance. The hospital is provided with operating theatre, anæsthetic room, X ray room, bath rooms, &c., and contains accommodation for some 25 patients. The administrative medical officer is Dr. W. J. Howarth; the consulting surgeon, Mr. D'Arcy Power; the consulting physician, Dr. Samuel West; and the resident surgeon, Mr. R. L. Mackenzie Wallis.

PAYMENT FOR FIRST-AID LECTURES IN IRELAND.—There has been considerable discussion among medical men in Ireland as to whether fees should be charged for the conduct of courses of instruction in first aid and ambulance work. Some men regard the delivery of such lectures as an offering to be given gratuitously for the good of the country. Others, not unnaturally, regard teaching of minor surgery and anatomy and physiology as a professional task deserving of pecuniary reward. In a great many cases it is pointed out the members of the first-aid classes are well able to contribute for the payment of their instructor. Moreover, the Department of Agriculture and Technical Instruction is devoting considerable sums of money for the upkeep of such classes as fulfil its requirements. The matter was considered at the last meeting of the council of the Irish Medical Association, and a resolution was carried to the effect that fees should be charged for the delivery of lectures on first aid and allied subjects. It has long been a rule of the British Medical Association that members should charge fees for such lectures.

THE INDIAN SOLDIERS' FUND.—An appeal has been issued by Lord Roberts on behalf of the Indian Soldiers' Fund, which has been established to provide the sick and wounded among our Indian troops at the seat of war with hospital accommodation in a warm climate and to furnish comforts such as additional warm clothing for Indian soldiers whilst in the field. For this purpose a subcommittee has been formed by the St. John Ambulance Association, with the approval of the Viceroy of India and the Secretary of State for India. It is proposed to set up a hospital of 500 beds at Alexandria, with a smaller subsidiary hospital at Marseilles. The honorary secretary's address is 1, Carlton House-terrace, London, W.

CANADIAN HOSPITAL FOR FRANCE.—The French official *Gazette* has published a decree authorising the Minister for War to accept a donation of £20,000 from the Canadian Government for the organisation and maintenance of a temporary hospital—to be called the Canadian Hospital—for sick and wounded troops.

THE Royal Westminster Ophthalmic Hospital has offered to the War Office ten beds for the use of the wounded suffering from injuries and diseases of the eye, and this offer has been accepted.

THE article on Open-air Hospitals in War Time, by Lieutenant-Colonel Robert Saundby, R.A.M.C. (T.F.), which appeared in THE LANCET of Sept. 19th, has been published in pamphlet form, price 6*d*., by Messrs. John Bale, Sons, and Danielsson, Limited.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—The annual meeting of the Royal Academy of Medicine in Ireland was held on Oct. 9th. The report of the Council stated that there were 162 Fellows and 21 Members, being eight Fellows and one Member less than in the previous year. The accounts showed a satisfactory balance in hand.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy held on Oct. 8th the following candidates were approved:—

Douglas Harris Anthony, St. Mary's Hospital; Geoffrey Thomas Baker, Middlesex Hospital; John Behesnilian, Charing Cross Hospital; Arthur Stanley Carter, Middlesex Hospital; Charles Theodore James Drobig, St. Mary's Hospital; Colin Charles Gordon Gibson, Guy's Hospital; Lionel Augustine Joseph Graham, Cambridge University and Guy's Hospital; William Clavering Hartgill, Charles Guy Hitchcock, and Alwyne Harold Manfield, London Hospital; Arthur Daniel Morris, University College Hospital; Arthur Geoffrey Morris, Bristol University; Edward Hugh Morris, Charing Cross Hospital; Newman Frederick Norman, St. Bartholomew's Hospital; Arthur Llewellyn Spencer Payne, Guy's Hospital; Claude Hollingworth Philips, London Hospital; Roberto Quesada-Jiminez and William Leonard Eliot Reynolds, Guy's Hospital; Edward Ebenezer Samaraweera, Ceylon Medical College and King's College Hospital; James Ernest Scanlan, St. Mary's Hospital; Henry John Hugh Symons, King's College Hospital; Ramon Romero SyQuia, London Hospital: and Harold Vickers, St. Mary's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery held on Sept. 29th and Oct. 1st and 2nd the following candidates were approved in the subjects indicated:—

Chemistry and Physics.—Alec Stuart Blacklaws, Guy's Hospital; Alfred Harold Bradbeer, Royal Albert Memorial College, Exeter; Eric Norman Commander, King Edward's School, Birmingham; Walter Samuel Hill, Bridlington Grammar School; Felix Reginald Knowler, Guy's Hospital; Stanley Herbert Lenton, Northampton School; Herbert Alfred Potter, Royal Dental Hospital; and David Errand Robinson and William Adam Woodward, Guy's Hospital.

Chemistry.—John Hulme Allwood, Liverpool University; Florence Goodman, Birkbeck College; John Herbert, Guy's Hospital; Bartle Leathlean, Bristol University; Ernest Findlay Shaw, Guy's Hospital; Robert Thorburn, Royal Dental Hospital; Joseph Frederick Weakley, Southend Technical School.

Physics.—Guy Harcourt Bowen, King Edward's High School, Birmingham; and Israel Jacobs, Bristol University.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Biology.—C. E. Clarke, Bombay.

Materia Medica and Pharmacy.—A. M. Berman, Belfast; C. H. Philips, London Hospital; and A. J. A. Wilson, Royal Free Hospital.

Anatomy.—A. M. Berman, Belfast; J. M. Forbes, Aberdeen; C. Gilroy-Jones, St. Mary's Hospital; E. M. Gooda, London Hospital; F. J. Harrington, Guy's Hospital; D. E. Hearn, Durham; R. F. Jarrett, London Hospital; H. D. L. Jones, St. Mary's Hospital; S. Mikhail, Cairo and Middlesex Hospital; J. B. Thomas, King's College; and L. J. Vincent, Cambridge and St. Mary's Hospital.

Physiology.—E. V. Beaumont, St. Mary's Hospital; A. M. Berman, Belfast; R. F. Jarrett, London Hospital; St. Mikhail, Cairo and Middlesex Hospital; T. F. Reason, St. Mary's Hospital; J. B. Thomas, King's College; and L. J. Vincent, Cambridge and St. Mary's Hospital.

THE late Surgeon-Major-General Robert Lewer, A.M.S., of Southsea, the valuation of whose estate is just announced, took part in Lord Roberts's march from Kabul to Kandahar.

MEDICAL MAGISTRATES.—Mr. F. S. Leech, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., and Mr. John Todd, M.R.C.S. Eng., L.S.A., were on Oct. 8th sworn in as justices of the peace at the Gateshead police-court.

Sir Robert M. Simon, after 35 years' service upon the medical staff of the Birmingham General Hospital, recently retired from the post of physician, and on Wednesday last was presented with his portrait, which will be hung on the walls of the hospital, and an illuminated address. At the same time Lady Simon was presented with a diamond tiara.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—A meeting of this society will be held to-day, Friday, Oct. 16th, at 8.30 P.M., at 11, Chandos-street, Cavendish-square, London, W., when a paper on the Classification of the African Trypanosomes Pathogenic to Man and Domestic Animals will be read by Surgeon-General Sir David Bruce, A.M.S., C.B., F.R.S.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Gay, S. B., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Shardlow District of the county of Derby.

Graham, J. M., F.R.C.S. Edin., has been appointed Specialist in Operative Surgery at the Military Hospital, Edinburgh.

Hawkins, Arthur, M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Physician to the Nordrach-on-Dee Sanatorium, Banchory.

Lawrence, H. H., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Patterdale District of the county of Westmorland.

Macnicol, M., M.D. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Leven District of the county of Fife.

Rollings, J. W., L.M.S.S.A., has been appointed Medical Officer of Health to the Luton District Council.

Scott, W. M., M.B., Ch.B. Edin., has been appointed Medical Officer of Health of Sittingbourne during the absence of Dr. T. B. Heggs on Territorial Service.

Williams, J. R., M.B., C.M. Edin., has been appointed Non-resident Medical Officer of the Conway and Penmaenmawr Joint Isolation Hospital at Groesynyd.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (*see Index*).

Birkenhead Borough Hospital.—Junior House Surgeon. Salary £100 per annum, with board and laundry.

Birkenhead Union Infirmary.—Female Resident Assistant Medical Officer. Salary at rate of £120 per annum, with board, washing, and apartments.

Birmingham City Asylum, Rubery-hill.—Junior Assistant Medical Officer. Salary £200 per annum, with apartments, board, laundry, &c.

Birmingham, Yardley-road Sanatorium and Anti-Tuberculosis Centre.—Third Assistant Medical Officer. Salary £200 per annum, with board and residence.

Bolton Infirmary and Dispensary.—Second House Surgeon. Salary £120 per annum, with apartments, board, and attendance.

Bradford Royal Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and washing.

Bristol City Asylum, Fishponds.—Second Assistant Medical Officer, unmarried. Salary £250 per annum, with apartments, board, washing, and attendance.

Bristol, Cossham Memorial Hospital, Kingswood.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

Bristol Royal Infirmary.—House Surgeon and House Physician for six months. Salary at rate of not less than £100 per annum, with board, apartments, and laundry.

Bury and District Joint Hospital Board.—Assistant to Medical Superintendent. Salary £200 per annum, with board, washing, and lodging.

Bury St. Edmunds, West Suffolk General Hospital.—Resident Medical Officer, unmarried. Salary £160 per annum, with board, lodging, and laundry.

Canterbury, Kent County Asylum, Chartham.—Junior Assistant Third Medical Officer, unmarried. Salary £250 per annum, with quarters, board, washing, &c.

Cardiff City Mental Hospital, Whitchurch, near Cardiff.—Second Assistant Medical Officer, unmarried. Salary £280 per annum and all found.

Chelsea Hospital for Women, Fulham-road, S.W.—Dental Surgeon.

Chesterfield and North Derbyshire Hospital.—Senior House Surgeon. Salary £140 per annum, with board, apartments, and laundry.

Chichester, Royal West Sussex Hospital.—House Surgeon, unmarried. Salary £110 per annum, with board, residence, and washing.

City of Westminster Union Infirmary, Fulham-road, S.W.—Second Assistant Medical Officer and Third Assistant Medical Officer. Salaries £160 and £140 per annum respectively, with board, residence, and washing.

Derby County Sanatorium.—Resident Assistant. Salary £250 per annum, with board, lodging, and laundry.

Dumfries, Crichton Royal.—Temporary Assistant Physician, unmarried. Salary at rate of 5 guineas a week, with apartments, board, laundry, and attendance.

Dundee Royal Infirmary.—Resident Medical Officer. Salary at rate of £40 per annum, with board, lodging, and laundry.

Durham County Hospital.—House Surgeon. Salary £150 per annum, with board, residence, and laundry.

Evelina Hospital for Sick Children, Southwark, S.E.—House Physician for six months. Also House Surgeon for four months. Salary at rate of £75 per annum, with board, residence, and washing.

Glasgow District Board of Control.—Resident Medical Superintendent for Mental Defectives, Stoneyetts, Chryston. Salary £300 per annum, with house, coal, light, &c.

Glasgow University.—Examiners.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

Great Yarmouth County Borough.—Assistant Medical Officer of Health. Salary £250 per annum.

Great Yarmouth Hospital.—House Surgeon, unmarried. Salary £140 per annum, with board, lodging, and washing.

Greenwich, Dreadnought Hospital.—House Surgeon and Casualty Officer. Salary at rate of £50 per annum each, with board, residence, and washing.

Guildford, Royal Surrey County Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

Hospital for Consumption and Diseases of the Chest, Brompton.—House Physician for six months. Salary £5 5*s.* per month.

Huddersfield Royal Infirmary.—Senior and Junior Assistant House Surgeons. Salary £80 per annum each, with board, rooms, and washing.

Hull Royal Infirmary.—Senior House Surgeon, unmarried. Salary £150 per annum, with board and apartments. Also Assistant House Surgeon. Salary at rate of £100 per annum, with board and lodging.

King's Lynn, Lynn and West Norfolk Hospital.—House Surgeon. Salary £150 per annum.

Leeds General Infirmary.—Ophthalmic House Surgeon for six months. Salary £50 per annum, with board, residence, and laundry.

Leeds Hospital for Infectious Diseases and Tuberculosis.—Assistant Medical Officer, unmarried, for six months. Salary at rate of £150 per annum, with board, lodging, and washing.

Leeds Public Dispensary.—Resident Medical Officer. Salary £130 per annum, with board, residence, and laundry.

Leicester Corporation Sanatorium and Isolation Hospital.—Resident Medical Officer. Salary £250 per annum, with board and residence.

Leicester Royal Infirmary.—Resident Assistant House Surgeons and Dressers.

Lincoln County Hospital.—Junior House Surgeon, unmarried, for six months. Salary at rate of £100 per annum, with board, residence, and washing.

Liverpool, Brownlow Hill Institution.—Resident Assistant Medical Officer. Salary £140 per annum, with apartments and usual resident allowances.

Maidstone, West Kent General Hospital.—Assistant House Surgeon, unmarried. Salary £100 per annum, with board, lodging, &c.

Manchester, County Asylum, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

Manchester Education Committee.—Female Assistant School Medical Officer. Salary £300 per annum.

Manchester, Hulme Dispensary, Dale-street, Stretford-road.—House Surgeon. Salary £180 per annum, with apartments, attendance, coal, and gas.

Manchester, Monsall Fever Hospital.—First Medical Assistant. Salary £225 per annum, with board, lodging, and washing

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

Manchester Royal Eye Hospital.—Junior House Surgeon. Salary £80 per annum, with residence, board, and washing.

Manchester Royal Infirmary.—Five Junior House Surgeons for three months. Board, residence, and laundry provided. Also Two Senior House Surgeons for six months, and Five House Physicians for three or six months, all unmarried. Salary at rate of £40 per annum, with board, residence, and laundry.

Manchester, St. Mary's Hospitals for Women and Children.—House Surgeon for Children's Department and House Surgeon for Obstetrical and Gynæcological Departments for three or six months. Salary at rate of £70 each per annum, with board and residence.

Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—House Surgeon. Salary £150 per annum.

Mount Vernon Hospital for Consumption and Diseases of the Chest.—Assistant Physician.

Newcastle-upon-Tyne Hospital for Sick Children.—Senior Medical Officer and Junior Medical Officer for six months. Salary £100 and £80 per annum respectively, with board, lodging, and laundry.

Newport (Mon.), Royal Gwent Hospital.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

Northampton County Asylum, Berry Wood.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

Nottingham General Hospital.—Assistant House Physician and Assistant House Surgeon for six months. Salary at rate of £100 per annum each, with board, residence, and laundry. Also Senior House Physician. Salary £120 per annum, with board, residence, and laundry.

Otago University, New Zealand.—Professor of Clinical Pathology. Salary £600 per annum.

Portsmouth Royal Hospital.—House Surgeon for six months. Salary £90 per annum, with board, &c.

Preston Royal Infirmary.—Assistant Resident Medical and Surgical Officer. Salary £120 per annum, with board, residence, and laundry.

Putney Hospital, Putney Common, S.W.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and laundry.

Reading, Berkshire Education Committee.—Assistant Medical Inspector of Schools. Salary £300 per annum.

Ryde, Royal Isle of Wight County Hospital.—Resident House Surgeon, unmarried. Salary £115 per annum.

Rotherham Hospital.—Assistant House Surgeon. Salary £125 per annum, with board, lodging, and washing.

Royal Waterloo Hospital for Children and Women, S.E.—Junior Resident Medical Officer. Salary at rate of £70 per annum, with board and washing.

Royal Westminster Ophthalmic Hospital, King William-street, West Strand, W.C.—Radiographer, part time only. Salary 25 guineas per annum. Also House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and laundry. Also Assistant House Surgeon. Salary (non-resident) £20 for six months, with part board.

St. Marylebone General Dispensary, 77, Welbeck-street, Cavendish-square, W.—Honorary Anæsthetist to the Institution and Anæsthetist to the L.C.C. School Dental Clinic. Also Honorary Gynæcologist, Temporary Honorary Ophthalmic Surgeon, and Honorary Medical Radiographer.

St. Mary's Hospital for Women and Children, Plaistow, E.—Female Resident Medical Officer and Female Assistant Resident Medical Officer. Salary at rate of £110 and £90 per annum respectively, with board, residence, and laundry.

St. Pancras Dispensary, 39, Oakley-square, N.W.—Resident Medical Officer, unmarried. Salary £105 per annum, with residence and attendance. Also Honorary Physician and Ophthalmic Surgeon.

St. Pancras South Infirmary, Cook's-terrace, Pancras-road.—Senior Assistant Medical Superintendent, &c. Salary at rate of £175 per annum, with board and apartments.

Salford Royal Hospital.—Resident Surgical Officer and Casualty House Surgeon for six months. Salary at rate of £120 and £100 per annum respectively, with board and residence.

Salisbury (General) Infirmary.—Assistant House Surgeon, unmarried. Salary £75 per annum, with apartments, board, lodging, and washing.

Scarborough Hospital and Dispensary.—Senior and Junior House Surgeons. Salaries £100 and £80 per annum respectively, with board, residence, &c.

Sheffield, East-End Branch of the Children's Hospital.—House Surgeon. Salary £120 per annum, with board and residence.

Sheffield Royal Infirmary.—Two House Surgeons and Assistant House Physician for six months. Salary £100 per annum each, with board and residence.

Shipston-on-Stour Union.—Public Vaccinator.

Southampton Free Eye Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

South Shields County Borough.—Assistant School Medical Officer and Assistant Medical Officer of Health. Salary £300 per annum.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Junior House Surgeon. Salary £115 per annum, with residence, board, and washing,

Staffordshire County Council, Cheddleton Mental Hospital, Leek.—Junior Assistant Medical Officer. Salary £270 per annum, with quarters, board, washing, and attendance.

Stirling District Asylum, Larbert, N.B.—Female Third Assistant Medical Officer. Salary £140 per annum, with board, &c.

Stroud General Hospital.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

Sunderland County Borough Education Committee.—Assistant School Medical Officer. Salary £300 per annum.

Sunderland Royal Infirmary.—Junior House Surgeon. Salary £100 per annum, with board, residence, and laundry.

Swansea Union.—Resident Assistant Medical Officer. Salary about £295 per annum.

Taunton, Taunton and Somerset Hospital.—Senior House Surgeon and Assistant House Surgeon. Salaries £120 and £80 per annum respectively, with board, lodging, and laundry.

Truro, Royal Cornwall Infirmary.—House Surgeon, unmarried. Salary £100 per annum, with rooms, board, and washing.

Wakefield, City of.—Temporary Medical Officer of Health. Salary £250 per annum.

Walsall and District Hospital.—Junior House Surgeon and Anæsthetist. Salary £110 per annum, with board, residence, and laundry.

Warrington Infirmary and Dispensary.—Junior House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.

West Ham and Eastern General Hospital, Stratford, E.—Senior House Physician. Salary £120 per annum, with board, residence, and washing.

Westmorland Consumption Sanatorium and Home, Meathop, Grange-over-Sands.—Second Assistant Medical Officer. Salary £175 per annum, with apartments, board, and laundry

West Riding County Council.—School Oculist. Salary £350 per annum.

Whitehaven and West Cumberland Infirmary.—House Surgeon. Salary £150 per annum, with board and attendance.

Wolverhampton Union Workhouse.—Resident Assistant Medical Officer and Medical Officer of Cottage Homes, unmarried. Salary £250 per annum, with apartments, rations, &c.

Worcester County and City Asylum, Powick, near Worcester.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Colchester, in the county of Essex.

New Addresses.

Hart, Neville, M.A., M.D. Cantab., Exeter Lodge, Exeter-road, Bournemouth. Telephone 1471.

A fee of 2s. 6d. is charged for the insertion of Notices of Change of Address, which must not exceed two lines.

Births, Marriages, and Deaths.

BIRTHS.

Dick.—On Oct. 3rd, at 6, West-street, Scarborough, to Dr. and Mrs. J. R. Dick—a son.

Neave.—On Oct. 7th, at St. Osyth, Colchester, Essex, the wife of Lionel Digby Neave, B.A. Oxon., M.R.C.S., L.R.C.P., of a son.

DEATHS.

Pern.—On Oct. 12th, at Botley, Hants, Alfred Pern, F.R.C.S., L.R.C.P., aged 70 years.

Rayner.—On Oct. 11th, at Brighton, after a short illness, Herbert E. Rayner, F.R.C.S., late of Camberley.

Notes, Short Comments, and Answers to Correspondents.

During the continuanee of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

THE CAMPAIGN AGAINST TUBERCULOSIS.

No doubt the chief means of combating the spread of tuberculosis is by the education of the patients and their friends. This object is in part carried out by the employment of well-trained health visitors to visit the homes of the patients so as to impart the necessary instruction and to render the living rooms as healthy as the circumstances will permit. The psychological factor, however, cannot be eliminated, and it will be found in actual practice that the patients will demand some treatment in the form of medicine. It is extremely difficult to convince them that anything can be done without the visits of a doctor. A medical officer will be found to be essential to control the treatment and further to instruct the patients as to their general mode of life.

A central institute of some kind, therefore, is necessary, where patients can apply in the first instance, and those able to come up for observation should do so, as it would be most difficult for one medical officer to visit regularly all the patients in their homes. Further, the examination of contacts would form a most important part of the scheme, and many of these could attend at the institution. At the same time, however, the institution (dispensary, or whatever it may be called) need be only of the simplest character, a waiting-room and consulting-room, which could be used as an office when the medical officer does not require it, being all that is really needed, although a room set apart for the examination of sputum is to be desired. The drugs required will be few in number. The value of tuberculin injections administered to ambulatory cases has not been definitely determined, and it would be unwise to discard them altogether.

To sum up: In any municipal scheme, properly trained health visitors to visit the homes of the patients are absolutely essential. A medical officer with special experience in tuberculosis is equally necessary, whilst the "dispensary" can be of a very simple character. Further, such an institution should be in touch with a hospital, where cases of a doubtful character might be admitted for purposes of diagnosis.

CUSTOM AND COURTESY.

To the Editor of THE LANCET.

SIR,—I was asked recently by the Prudential Assurance Company to examine and report on the health of two panel patients in this town, the name which I do not give except to you. I wrote to the two doctors in question stating that I had been so requested, and that I should be pleased to meet them. Neither replied, and I examined and reported in due course. I take it that it will not be necessary for me to write to either of these medical men again if I am asked to examine other of their patients.

I am, Sir, yours faithfully,

D.

Oct. 13th, 1914.

⁂ We recommend our correspondent to send the notifications which courtesy demands, whether the courtesy is reciprocated or no. Mr. H. Bazett's letter in THE LANCET of Sept. 5th, p. 680, should be read.—ED. L.

A SAFEGUARD IN THE DARKENED STREET.

TRAFFIC at night, both vehicular and pedestrian, is becoming increasingly difficult and dangerous owing to the very limited lighting arrangements imposed upon us by military necessities. Accidents have already been recorded, and we make bold to offer a suggestion to our authorities, which, if acted upon, would, we think, lessen these dangers without being of any advantage to the enemy. In streets or crossings where there is considerable traffic we suggest that the kerbing of the pavement should be whitewashed. This plan was adopted on the edge of the platforms some years ago by the Underground Railway with great advantage to the public and a reduction of the accident list.

Some of our streets are so dark that it is difficult to see where the pavement ends and the road begins. Such a plan, surely, would be of great assistance to the public and to vehicular traffic also, and its adoption would, we imagine, entail little expense. We quite see that the whitewashing would require frequent renewing, and we only suggest that the process should be employed in selected spots.

A QUOTATION IN SEARCH OF A FATHER.

To the Editor of THE LANCET.

SIR,—I have been unable before this to express my thanks to Dr. H. P. Cholmeley for his letter in THE LANCET of Sept. 26th in answer to my inquiry. It has introduced me to a very amusing book which I had never seen before, and incidentally to some wonderful derivations. Moreover, his reference to Upper School days suggested to me the source whence I got the quotation in question. It is given in Macleane's Horace, Sat. II., iv., in a note on the words, "pratensibus optima fungis Natura est: aliis male creditur." But the place is not a library at Vienna, but a monastery at Vallombrosa.—I am, Sir, yours faithfully,

EDWIN A. EADE.

United University Club, Pall Mall East, S.W.,
Oct. 7th, 1914.

FLY LARVÆ IN MANURE.

THE United States Department of Agriculture has recently experimented with a view to finding a non-poisonous substance which should be destructive to fly larvæ and have no injurious effects on manure. Among the substances tested were kerosene, iron sulphate, potassium cyanide, formaldehyde, calcium cyanamid, pyroligneous acid, common salt, copper sulphate, lime-sulphur mixture, Paris green, sodium fluorid, several proprietary disinfectants, and borax. Commercial borax was found to be the most effective, practical, and economical, and the weekly bulletin of the Chicago Department of Health gives the following directions for its use. Apply 1 lb. of borax to every 12 bushels (15 cubic feet) of manure immediately on its removal from the barn. The borax should be applied particularly around the outer edges of the pile with a flour sifter or other fine sieve, after which two or three gallons of water should be sprinkled over the borax-treated manure.

BETEL AND COCAINE.

To the Editor of THE LANCET.

SIR,—With reference to a recent paragraph entitled "Misri and Supari," referring to supari (betel nut) being supplied as a masticatory to the natives of India, I would point out that if our Indian troops spread the use of betel nut chewing as a habit a warning may be necessary. Your own India correspondent has said that at one time in Calcutta the drug (cocaine) was sold in two-pice packets and was retailed almost openly by the army of betel sellers. The betel sellers, it appears, put 1 grain of cocaine into the other ingredients of the *pan* (the *pan* is the betel leaf), so that many persons who would be most indignant if charged with being cocaine eaters are gradually acquiring a taste for the drug unknown to themselves.

I am, Sir, yours faithfully,
London, Oct. 10th, 1914. OBSERVER.

CHEMICAL INDUSTRIES.

THERE have been several references in the daily press recently to the German chemical industries. A few facts and figures taken from the German Year Book for 1914 show the strides that Germany made during the past 33 years. For instance, in 1880, their exports of chemical products were valued at £11,850,000, and in 1913 at £47,820,700. The number of employees doubled since the year 1895, being now over 280,000. The exports were made up of the following chemical products: chemical bases, acids, salts, £18,854,400; colours and dye stuffs, £13,402,200; varnishes, lakes, cements, &c., £367,900; ether, alcohols, essential oils, perfumery and cosmetics, £2,220,200; artificial manures, £2,710,600; explosives, £3,702,700; other chemical pharmaceutical products, £5,062,800. The editor says: "It is gratifying to see that the chemical industry enjoys great prosperity. The 308 joint stock companies in 1912 commanded a paid-up capital of £33,310,000, with reserves amounting to £9,920,000. The average dividend 13·95 per cent. was the highest in all branches of trade, except insurance."

ANTITYPHOID INOCULATION.

AS there is so much discussion at the present juncture over the question of antityphoid inoculation for soldiers it may be worth mentioning that in Mr. Stephen Paget's new book, "Pasteur and After Pasteur," there is a good summary of the subject on pp. 128-35. Particularly forcible is the instance of the epidemic of 1912 in the barracks at Avignon, in which out of 2053 men 1366 were protected and 687 were not. In the unprotected minority there occurred 155 cases with 21 deaths; in the protected majority not one case, though living as they did in conditions otherwise precisely identical, they ought on that basis to have had 308 cases with over 41 deaths.

MOONSTRUCK.

To the Editor of THE LANCET.

DEAR SIR,—I beg to inform you that I have discovered a theory regarding Lunacy, which will if true cure all Lunatics. It is caused by the attraction of the moon which draws all the blood to the head and causes conjestion. The heart being weak is unable to pump blood away.

If stimulents were given a cure would be the result.

Yours truly,
Great Northern Hotel, King's Cross. JAS. S. LEE.

⁂ The above letter reached us by registered post with the postmark "Redcar."—ED. L.

PRUSSIAN MILITARY STEP.

THE military step, or tempo, or rate of marching is interesting from the point of view of the rate of fatigue of troops. In the eighteenth century the step was usually reckoned as 63 centimetres long and 80 to the minute in ordinary marching, with 140 to the minute for the "double step." In the Prussian orders for 1847 this was altered to 108 steps for the ordinary march and 120 for the bayonet charge, and each step of 75 centimetres long. Later it was altered to 112 steps for the ordinary march. Now the step is usually 80 centimetres long, 112 per minute for the ordinary pace, 120 for the accelerated pace, and 165 to 175 steps per minute each of one metre in running. What the rate of retreat is in cases of necessity is not defined.

WANTED—SUGGESTIONS FOR TREATMENT.

To the Editor of THE LANCET.

SIR,—May I ask for advice through THE LANCET on treating the following case: A heavy woman, 44 years of age, has pain in one heel on pressure and when standing or walking, not when resting or in bed. Any suggestions will be much appreciated.—I am, Sir, yours faithfully,

Chelmsford, Oct. 13th, 1914. JOHN L. MARTIN.

MISSING.

Joseph George Hole, a postman, of Chobham, Surrey, was last seen at Brighton on July 6th. The parents think that perhaps their son may be in some place ill, and would be obliged if any doctor could give them information of his whereabouts. The missing man is described as follows: age 36, height 5 ft. 8 in., fresh complexion, dark hair and moustache, false teeth, first two fingers of right hand deformed. It is thought that he may be suffering from loss of memory. Information may be given to the police at Chobham.

ENGLISH-MADE MEDICINALS.

Messrs. Burroughs, Wellcome, and Co. announce that they are able to supply cocaine and cocaine hydrochloride manufactured throughout at their "Wellcome" chemical works at Dartford in Kent. They also prepare at the same place ernutin (the essentials of ergot) and a series of glycerophosphates, the calcium, iron, magnesium, potassium and sodium salts.

AN INSURANCE PHARMACOPŒIA.

AN addition to the crop of Insurance Act literature is "Standard Prescriptions for Insurance Practice," by Dr. C. H. Gunson, of the Isle of Ely Insurance Committee. It is a useful little formulary with the ordinary type of collyria, gargles, lotions and sprays, and mixtures, pills, ointments, powders, &c. There is evident rather a tendency to polypharmacy, prescriptions containing six or seven ingredients being fairly frequent. It is thought that the adoption of a book of this character by doctors and dispensers will save much tedious writing. That may benefit the doctor who uses it, but unless all the panel doctors in the locality agree in the selection of the same formulary the chemist's time would seem to be fully occupied in hunting up each particular doctor's formula and making up the particular brand of, say, mistura bismuthi ordered therein. To be a real time- and effort-saver to both chemist and doctor the formulary must be generally used, and that is hardly likely to be the case unless it is drawn up by common consent by the local practitioners or is selected for use by authority. Dr. Gunson's little book is published by the Scientific Press, Limited, and the price is 1*s*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Harveian Oration

ON

ADVANCES IN KNOWLEDGE REGARDING THE CIRCULATION AND ATTRIBUTES OF THE BLOOD SINCE HARVEY'S TIME.

"FOR THE LIFE OF ALL FLESH IS THE BLOOD THEREOF."

Delivered before the Royal College of Physicians of London on Oct. 19th, 1914,

BY SIR RICHARD DOUGLAS POWELL, BART., K.C.V.O., M.D., F.R.C.P., LL.D.,
PHYSICIAN IN ORDINARY TO THE KING; CONSULTING PHYSICIAN TO THE MIDDLESEX HOSPITAL AND THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, ETC.

MR. PRESIDENT, FELLOWS, MY LORDS, AND GENTLEMEN,—Some of us may recall the picture by W. Yeames, R.A., portraying our great master Harvey absorbed in study whilst the battle of Edge Hill, timorously watched by his Royal pupils, is raging within a bowshot. So may we now, perhaps without reproach of cynicism, detach ourselves for an hour in contemplation of some of the beneficent gifts to medicine that have ensued from Harvey's work, whilst we with well-nigh the whole world are steeped to the skies in a war to which science has given the last touch of horror and carnage.

INTRODUCTORY REMARKS.

By the request with which, Mr. President, you have honoured me that I should give the Harveian Oration this year you have placed me under deep obligation, for you have put me in communication with the spirit of Harvey—a great man—as it shines out in his works, as it sheds light upon the thoughts of the centuries that went before, and as it illumines the paths of progress that radiate onwards from his time. And although, Sir, your command is the 258th that has reached the Fellows of this College, yet so numerous are the branches of thought and inquiry that have emanated from Harvey's discovery, as the spreading tree from a single pregnant germ, and so ever living and extending is each branch of that tree of knowledge, that year by year some advancement has been found with a freshness of interest worthy of record in this College. In my respectful response to your invitation I will endeavour to trace the progress and growth of one or two of those branches of knowledge that have emanated from Harvey's root, and have reached our time with their new buds of fresh development, each endowed with a spirit of further growth and increase.

Dr. Edmund Parkes, my revered teacher, in his Harveian Oration, the latest words of his beautiful life, which were read to this College by Sir W. Jenner, commences with the question, Will the name of Harvey be echoed down the stream of time with deathless fame? And his answer is, Yes. Harvey's discovery is a landmark for all time as "one of those cardinal discoveries which lie at the very foundation of physiology and medicine." Parkes proceeds to say: "The full interpretation of this great discovery is even now not given, for we are still painfully learning what the blood does in that marvellous circuit which never ends, yet ever recommences."[1] It is this theme of what the blood does that I would wish chiefly to pervade my address to-day.

Sir W. Church observes that although the knowledge of anatomy reached a considerable degree of perfection at the hands of Aristotle, Galen, and later in the sixteenth and seventeenth centuries, of Silvius, Vesalius, Fallopius, and Fabricius, yet, "from the time of Aristotle to that of Harvey no advance was made in physiological knowledge, if indeed it had not receded, and that as Aristotle must be regarded as the first of the biologists, so Harvey was the founder of physiology."[2] The late Dr. Ogle remarks: "And upon Harvey's discovery as a new 'primum mobile' rests, in fine, all our knowledge of pathology, and much of our knowledge of the action of remedies."[3]

The Master Mind and Scientific Discoveries.

The visitation of genius may in a sense be defined as a divine touch in a ready environment. We do not know at exactly what period Harvey attained the conception that quickened and directed his life's work. Dr. Ogle was very right in disputing the statement of Willis that the discovery of the circulation came fully from him. "This view," Ogle continues, "cannot be held. The discovery was, like all other scientific discoveries, the result of the growth of germs sown long before. It was not the work of one mind."[4] True; but it required the master mind of Harvey to collect and collate the numerous detached observations of his teachers and contemporaries to a discovery he had already adumbrated. Such is the case, perhaps, with regard to all epoch-marking discoveries: Newton's conception of gravitation, Priestley's oxygen, Simpson's anæsthetics, Lister's antiseptic system, Koch's discovery of the bacillus tuberculosis were all effected in an atmosphere of thought and experiment highly charged with expectation and speculation in the direction of the particular discovery.

It is said by the Psalmist, "When the breath goeth out of a man he returns to his dust and all his thoughts perish." But whilst the man may think no more, his thoughts live for good or evil to strive with other thought in the sentient atmosphere that gathers about the centres of civilisation and progress.

> Our thoughts are ours, their ends none of our own.[5]

Harvey's sentient atmosphere was shared by great anatomists and ardent pioneers of thought. Servetus had already described correctly the circulation through the lungs, although Harvey never saw his work. This fecundity of thought is finely expressed by Shakespeare in the words of King Richard—

> My brain I'll prove the female to my soul;
> My soul, the father; and these two beget
> A generation of still breeding thoughts,
> And these same thoughts people this little world;
> In humours, like the people of this world,
> For no thought is contented.[6]

The Character of Harvey.

It is unnecessary again here to describe—as has often been done—the features and character of Harvey. It must be said, however, that he was a man dominated by an ardent and imperious spirit. His mind was naturally practical and forward looking—a mind educated by wide culture and reading from the old authors, especially Aristotle, Hippocrates, and Galen. He read all with his critical faculty well awake; and in regard to physiology and medicine, which were the objects of his life's work, he accepted nothing on mere authority, but by logical analysis and by actual experiment tested all the conclusions which interested him. His outlook was ever onward from laboriously accredited or discovered facts to the conclusions to which they pointed and to the fresh inquiries and experiments they might prompt. In this respect he was in marked contrast to his great contemporary in this College, Sir Thomas Browne; and I say this in no disparagement to Sir Thomas, who was indeed Harvey's superior in scholarship. The two minds were essentially different—the one contemplative, retro- and introspective, the other practical, inquiring, strenuously objective and forward-looking; each is supplemental to the other, but perhaps an impetus was given to the objective order of mind with the revival of learning under conditions of increasing freedom from the restraint of ecclesiasticism. We are fortunate in having both classes of mind present with us to-day. We may in our own College recall the names of Linacre, Sir Thomas Browne, Richard Mead, and Caius for their purity of language and enrichment of literature from the stores of traditional learning; whilst those of Harvey, Sydenham, Willis, Bright, Addison, Jenner, and Jackson may be especially remembered amongst the great pioneers and teachers of medicine.

[2] Harveian Oration, 1895, Sir W. Church, pp. 14 and 15.

[3] Harveian Oration, 1880, John W. Ogle, p. 28.

[4] Ibid.

[5] Hamlet, Act II., Scene 2.

[6] King Richard II., Act V., Scene 5.

Not only in medicine but equally in other sciences—including political science—may this characteristic, pregnant of the future, be observed. As instances of recent pioneers of action may be mentioned the names of Lord Strathcona, Cecil Rhodes, and Joseph Chamberlain, amongst others, who were "for ever moving forward with reverence for the past, with care to guard its great traditions, but ever seeking in the future something better, something nobler, something greater than that which we now enjoy."[7]

The Medical Profession and New Discoveries.

We hear it often said of the medical profession that new discoveries are met by captious criticism and ungenerous distrust. This has been the subject of comment by many Harveian orators. Sir James Alderson remarks in reference to the obstruction and neglect with which Harvey's work was greeted: "Yet it may be questioned whether difficulties in the establishment of any new truth ought to be esteemed a hardship. New knowledge must be proved; and too facile acceptance can be wished for only by promulgators of error."[8] Sir Edward Cook in his "Life of Florence Nightingale" makes the remark: "Controversy is perennial between those who ascribe the course of political or social history mainly to great men, and those who ascribe it rather to streams of tendency. It is less open to controversy to say that the great men who leave the more permanent mark upon history are those whose genius conforms to the spirit of their time, but who are yet a little in advance of their age."[9]

Controversy quickens thought and strengthens understanding, and all great pioneers, like Harvey, Darwin, Spencer Wells, and Lister, have shown their recognition of this truth. This is the true attitude, especially for pioneers in medical science. No one in a grave and responsible profession can expect to promulgate a new doctrine carrying with it, it may be, fateful results to human beings, without being prepared to sustain with equanimity the ordeal of ardent criticism, to suffer patiently even the obstruction of fools, until he can convince by demonstration the minds of all. Harvey has given to us a great lesson on this patient striving with criticism, pursuing his arguments without bitterness, and strengthening them to conviction with sweet and laborious persuasiveness.

The Origin of Life.

Harvey speculated much on the immediate source of life. He recognised, however, its general origin in ova, and presumes that this may still be so in even the minutest organism far beyond his vision. "Let physicians therefore cease to wonder at what always excites their astonishment—namely, the manner in which epidemic contagions and pestilential diseases scatter their seeds and are propagated to a distance through the air, or by some 'fomes' producing diseases like themselves in bodies of a different nature and in a hidden fashion silently multiplying themselves by a kind of generation (until they become so fatal), and with the permission of the Deity spread destruction far and wide amongst man and beast; since they will find far greater wonders than these taking place daily in the generation of animals."[10]

He thus clearly recognises the generative elements in minutest nature, and he is not disposed with Hamlet at the same time to admit and to question "if the sun breeds maggots in a dead dog being a God kissing carrion," but frankly recognises the germinative edict of the Creator "as if it were said by the Almighty 'let there be progeny' and straight it is so." "A superior mind and more divine agent than man," he later on observes, "therefore appears to engender and preserve mankind, a higher power than the male bird to produce a young one from the egg ...... to none can these attributes be referred save to The Almighty first cause of all things, by whatever name this has been designated—the Divine Mind by Aristotle; the Soul of the Universe by Plato; the Natura Naturans by others; ...... by ourselves, and as is seeming in these days, the Creator and Father of all that is in heaven and earth, on whom animals depend for their being, and at whose will and pleasure all things are and were engendered."[11]

SOURCE OF CARDIAC ENERGY.

Since Harvey dispelled the views of Hippocrates, Aristotle, and Galen, which prevailed for 2000 years, that the operative force of the heart was in diastole, opinions have alternated as to the source of cardiac energy. Harvey did not discuss the matter, but observing the contractile spot as the motor force of the circulation at the fourth day of the life of the chick *in ovo* assumed it to be an intrinsic rhythmic function of the ventricle. Some observers, with Haller, agreed with Harvey's view that it was intrinsic in the cardiac muscle. Others, with Legallois (1812) and Remak, have regarded it as derived from nervous stimulation either from outside the heart or originating in ganglia first discovered by the latter observer within the heart in 1844, at about the time that the brothers Weber demonstrated the restraining influence of the vagus upon the heart. Gaskell in 1881 again demonstrated this myogenic activity of the heart, and he regarded the ganglia within it as inhibitive. This view was strengthened by the later researches of Engelmann, and it is now generally agreed that the ganglia and nerves of the heart with their corresponding centres are for the purpose of regulating the functions of that organ.

The Rhythmic Function of the Heart.

After careful observation on the hearts of tortoises Harvey concluded that the automatic rhythm of the heart's contraction commences at the venous end, spreading to the auricle and then to the ventricle in a very definite manner. Purkinje, Kölliker, Gaskell, Kent, Tawara, and Keith and Flack, with all the wealth of research at their command, would seem to justify this general view; and they have further shown that there are in the heart centres of neuro-muscular tissue more embryonic in character than the adjacent textures, and which are in continuity with a bundle of fibres, the band of His. This band, dividing above the septum, distributes branches throughout the subendocardium, the fibres of which are identical with those described by Purkinje and minutely examined by Kölliker and terminate mainly in the papillary muscles of the ventricles. Only the elaborate methods and instruments of modern physiology could have elucidated these important points.

It is then evident that the rhythmic function of the heart muscle is a coördinated neuro-muscular force still inherent in the sino-auricular and auricular nodal sarcoplasm and carried onwards by the auriculo-ventricular band; it is a survival of the neuro-sarcoplasmic function of the heart before any extrinsic nervous system existed, exhibited in the first contractile spot of the chick noted by Aristotle and so closely investigated by Harvey; and that the extrinsic nervous mechanism of the heart has been gradually developed as the requirements of the organism have become more complicated. The continuity and incorporation of this more elemental neuro-muscular tissue with the striated fibres of the heart is beautifully shown in some of the illustrations in Tawara's monograph (Plate IV., Figs. 6 and 5). Thus the myogenic and neurogenic views of the heart's action have become, we may hope, finally merged and reconciled.

That the first beat of the heart is really ventricular, as concluded by Harvey from his observations of the chick at the fourth day, is not altogether improbable, although Harvey himself in later observations of the tortoise describes vermicular movement extending from the sinus venosus and completed by the ventricular systole. It is interesting to note in this connexion an observation by Dr. Pavy,[12] which is referred to in the late Professor Rolleston's Harveian Oration (1873), pointing out that in the dog a sudden impulse is given to the auricles by the violent contraction of the ventricles which appears to start their vermicular contraction. It may seem little more than a matter of account whether the heart's action initiates with ventricular systole, the shock of which starts the mechanism of diastolic filling, or whether it is a vermicular action culminating in a powerful systole. A practical interest is, however, given to the question by comparatively recent observations with the electric cardiograph, which show that the auricles are not infrequently put completely out of action, as in the auricular fibrillation described by James Mackenzie and figured in the electrical tracings of Hill, Lewis, and others; and yet the circulation goes on by ventricular action alone, the auricles being converted into mere passive tubes.

Much valuable work from a therapeutical point of view was done in Ludwig's laboratory and by the late Dr. Ringer in discovering the effect of certain saline solutions, especially the chlorides of sodium, calcium, and potassium, in maintaining the irritability of cardiac muscle. A certain mixture of these salts for this purpose is still known as Ringer's saline solution.

The Reaction of Cardiac Muscle.

Amongst the differences in the reaction of cardiac muscle and skeletal muscles to stimulus there is one which is no doubt of some importance, but to which a misleading prominence is given in most text-books of physiology. It is known as the "all or nothing law" of Bowditch. It was found by Bowditch and Ranvier that a portion of muscle detached from the heart of a frog, when electrically stimulated, contracts at once with its full power and that a stronger stimulus will not have any further effect, differing thus from the graduated force of contraction of skeletal muscle according to strength of stimulus, and the conclusion is drawn that if the heart contract at all its contraction is maximal, "for all it is worth."

Even if this observation be trustworthy it will not apply to the living heart under vital conditions of innervation. As pointed out in Howell's "Textbook of Physiology" (p. 573), "numerous observers have called attention to the fact that the vagus fibres may also cause a weakening in the force of the beat as well as a slowing in the rate, or, indeed, the two effects may be obtained separately." In no other organ of the body is there a more manifest reserve of functional power to meet the exigencies of varied conditions of effort, of arterial resistance, of emotion, of sudden or gradual valvular defect or other vicissitudes of life.

It is to be noted that later observations have disclosed another peculiarity of heart muscle unknown to Bowditch at the time of his experiments—namely, that at the time of contraction the heart muscle is "refractory" to further stimulus. It is possible that this fact may vitiate the conclusions drawn from electrical stimulation of heart muscle, and I do not know whether it has been allowed for.

EFFECT OF LUNG ELASTICITY ON THE CIRCULATION.

In addition to the driving power of the ventricles, roughly recognised as equivalent to 6 and 3 inches Hg respectively, there are certain further aids *a tergo* to the circulation which may be briefly enumerated. They are partly sustaining and partly supplementary. The driving power is sustained and carried on with least possible loss (1) by the elastic recoil of the great vessels upon their closed valves; (2) it is said (Lauder Brunton and T. D. Lister) that there is a certain rhythmic or rather peristaltic contraction of the smaller vessels which has some slight effect in propelling the blood through the veins; (3) the larger veins being sheathed with their corresponding arteries are compressed with each arterial systolic expansion, and the blood restrained from back flow by the valves is thus propelled onwards towards the heart; (4) during exercise the contraction of the limb and trunk muscles compresses the venules and larger veins and similarly urges on the venous current; and (5) the compressing effect of abdominal, perineal, and diaphragmatic muscles under various twisting, bending, and straining movements has the same influence upon the great reservoirs of blood in the abdominal veins, the direction of all these forces being determined by valves.

---

[12] Medical Times and Gazette, Nov. 21st, 1857, p. 521.

It is a matter for great regret that Harvey's observations on respiration and the greater part of his observations on medicine have been lost through destruction by fire and the malice of a political mob. It is hardly likely that with his extraordinary perceptive powers he could have failed to note and to comment upon the *vis a fronte* aid to the circulation which is derived from the aspiratory traction of the lung elasticity upon the mediastinal space.

Physicians and anatomists before Harvey's time regarded the lungs as a power in the movement of the blood, but they erroneously thought that blood and air were impelled to the heart by the compression of the lungs in the act of expiration. Perhaps even modern physiologists and clinicians have not fully grasped the agency of the elastic traction of the lungs as a constant force of low tension, increased with every inspiratory movement, diminished but not wholly extinguished during expiration, tending always to attract blood through the central veins to the heart cavities, and thus steadily and perpetually aiding the venous return.

The Dynamics of Respiratory Movements.

Up to and at the time of Hutchinson's well-known paper read before the Royal Medical and Chirurgical Society in 1846 the dynamics of respiratory movements were not rightly formulated. Hyde Salter, a Fellow of this College, who first pointed out in 1865 that the elasticity of the ribs was in ordinary breathing a factor in aid of, not against, inspiration, had had his attention especially drawn to the mechanism of respiration by his own sufferings from asthma. This traction of the ribs in aid of inspiration—as I have endeavoured to point out—is throughout the respiratory act never entirely lost in calm breathing, although it tends to become neutralised as the chest enlarges with inspiration. Salter pointed out that in the cadaveric position of expiration there was an outspring of the ribs when released from the traction of the lungs equal to 1/100 inch or 0·25 mm. Some experiments I made in 1876 led me to regard this outspring as equal to from 1·6 to 3 mm. Hutchinson, and later Burdon Sanderson, estimated thoracic expansion in ordinary breathing at about 1·6 mm. Hence practically the thoracic movements in ordinary breathing oscillate within the range of thoracic outspring, leaving this factor constantly on the side of the inspiratory forces. The diaphragm, attached like a bowstring to the elastic margin of the thorax, is similarly held in a state of arched tension by the traction of the lungs.

The result of this elastic mechanism is that the respiratory act in both directions commences with perfect automatic smoothness and imperceptibility. Another effect is to protect the lungs from pressure. There are several other important considerations that arise out of this mechanism in diseased conditions of the respiratory organs. But I am concerned now chiefly with the circulation, and especially as it is affected by these agencies having their root in lung elasticity.

The traction exercised upon the mediastinum and those contents of it which are not in communication with the outer air—the heart, arteries, veins, and lymphatics—is estimated as equal to from 4 mm. in expiration to 7 mm. Hg in inspiration.[13] (It has been stated that this effect is not wholly lost even in the peripheral veins, being appreciable in the small veins by the side of the tendo Achillis.[14]) The positive blood pressure within the great veins as they enter the thorax is well-nigh exhausted, and in the lymphatic currents it is still less, so that this *vis a fronte* equivalent to from 4 to 7 mm. of mercury, being in constant action, is of considerable value in drawing onward the sluggish venous current to refill the auricles and ventricles during diastole.

It is said that at the very commencement of diastole the ventricles have a certain suction power supposed to be due partly to recoil, partly to an erectile effect upon the muscle produced by the influx of blood through the coronary arteries. This aid to the refilling of the ventricles is, however, but momentary and slight and probably does little more than help to open the auricular valves.

Influence on the Heart in Disease.

In health the powerful muscular ventricles during systole can easily disregard any impediment to their contraction caused by the negative pressure in the mediastinum. Such impediment can only be noted by fine instruments as a slight lowering of the blood pressure during inspiration.[15] But in cases of failing heart power, and especially when attended with over-distension of the right cavities, the vacillation of systole with each inspiration becomes so marked that the respirations can be easily counted by the remissions of the pulse force. In extreme cases complete failure of the pulse is observed with each inspiration. This phenomenon must be familiar to physicians. I have pointed it out to students and practitioners for many years as an important and ominous sign of failing heart power. In certain conditions it would be an argument in favour of relieving the venous fulness of the right cavities by bleeding, whilst stimulating heart power by strychnia and oxygen.

We bear witness to the value of this *vis a fronte* force in the use of respiratory exercises as an aid to cardiac action and development in feeble, dilated hearts, especially in children, and for the fatigued hearts of adults. We witness clinically the embarrassment which arises in emphysema from the diminished aid from this force to the circulation. Only in extreme and dangerous fluid effusions and pneumothorax does the pulmonary tension, however, become wholly exhausted and the compression of the lung suggested by Galen and apparently accepted by Harvey operative.

The Right Ventricle.—Arteries after Death.

It may be noted that as the systolic work of the right ventricle is distributed within the thorax the pulmonary arterial pressure is not affected by the respiratory mechanism under consideration (except when possibly some fluctuations occur in the capacity of the pulmonary capillaries). The diastolic supply to the right ventricle is, however, greatly aided by aspiration through the great veins.

---

[13] Howell's Text-book of Physiology, p. 649. Professor Starling places it at 10 mm. Hg during expiration and even 30 mm. Hg on forcible inspiration.

[14] System of Medicine, Allbutt and Rolleston, vol. vi., Thrombosis, by W. H. Welch, M.D., p. 717.

[15] It must be here remarked that Professor Starling considers that the blood pressure is increased at least during the latter two-thirds of inspiration. He illustrates this view in a diagram, but I am not clear that the diagram represents an actual measurement and venture to think on the clinical grounds above stated that this view needs further verification. The view adapted in the text is upheld by Leonard Hill. (The Vascular System and Blood Pressure: Further Advances in Physiology, 1909, p. 145.)

Although Harvey pointed out the fallacious inferences drawn by the old anatomists from the supposed occupation of the arteries by air during life he never seems to have denied that the arteries were so occupied after death or realised that only with the first division of an artery by the anatomist's knife is air admitted to them. It is possible that the extreme expiratory contraction of the chest so constantly observed at death is connected with the emptying and collapse of the great intrathoracic arteries and the attempt to restore atmospheric equilibrium. And it is in this connexion interesting to observe that after death the great vessels, when occupied at all by ante-mortem clot, are so occupied by a clot much smaller than their calibre.

INSTRUMENTAL METHODS.

It may be said that the great advances in knowledge respecting the circulation since Harvey's time have been made through the aid of instrumental methods. When the pocket lens of Harvey was replaced by the primitive microscope of Malpighi the capillary link of the circulation which could only generally be assumed by Harvey was demonstrated.

The systemic blood pressure was first roughly but very accurately estimated by the Rev. Stephen Hales (1773), and by simple experiments he also demonstrated contraction and relaxation of the vessels as influencing the output or blood pressure—no small feat in a man of his time and with but little medical training. Next to the general blood pressure the recognition of its local distribution according to the requirements of the different organs was an epoch-making event in the history of discovery, which was inaugurated by the memorable experiments of Claude Bernard upon the chorda tympani nerve in 1851.

The Local Distribution of the Blood.

The fact of such varied distribution to organs and tissues under conditions of emotional and functional stimuli had not altogether escaped Harvey. He commented upon the pallor or flushing of the face under the emotions of self-consciousness, fear, anger, or shame, and he observed that the ears might be red when the face was pale; he was, moreover, aware of some connexion of the nervous system with the local disturbances of circulation caused by irritation. He comments upon the fact in association with stomach and other abdominal irritations, and in his remarks upon the effect in his own person of a poisoned needle puncture clearly shows his appreciation of this agency. Having pricked his hand at one point with a clean needle and at another with one envenomed with spider poison, he remarks: "I could not by my simple sensation perceive any difference between the two punctures; nevertheless, there was a capacity in the skin to distinguish the one from the other; for the part pricked with the envenomed needle immediately contracted into a tubercle, and by-and-by became red and hot and inflamed, *as if it collected and girded itself up for a contest with the poison for its overthrow.*"[16] The careful observations upon Alexis St. Martin perhaps first demonstrated the accession of blood to organs in activity. The importance of nervous control in regulating general blood pressure was more fully recognised by the discovery by Ludwig in 1866 of the depressor nerve as an afferent nerve of the heart which, when stimulated, as by excessive blood pressure within the heart and aorta, caused through the medium of the splanchnic nerve a dilatation of the abdominal arterioles with instant release of intracardiac pressure.

It would take more than one address to illustrate in detail the many results and conditions of flushing and restriction of circulation through the different organs and tissues as required for their individual functions. We now fully recognise how efficiently the blood is held in the grasp of the arterial system, to be distributed here or there in accordance with local needs telegraphed to the nerve centres from the several organs; and our knowledge of the details of this control with regard to individual organs is ever increasing, in witness of which I might quote Dr. Markwalder's and Professor Starling's recent researches showing how the coronary circulation of the heart itself is thus regulated by some local mechanism in accordance with the demands upon its functional capacity.[17] These observers find that the coronary circulation is intimately dependent on the general arterial pressure; that adrenalin causes dilatation of the coronaries, as it raises arterial pressure; that increase of CO_2 in the blood also causes coronary dilatation; and that non-volatile metabolites produced by the heart muscle are potent agents in causing a similar dilatation.

The presence of the same neuro-vascular mechanism in the lungs and brain has long been conjectured by physicians as necessary to explain certain symptoms—apnœic, aphasic, convulsive—which are familiar in practice. Such mechanism has been long and even recently denied, but has been demonstrated to exist by the successive observations of Sir John Rose Bradford, Dr. Bokenham, Sir Lauder Brunton, Roy and Sherrington, Brodie and some others, and affirmed by Sir David Ferrier in his Harveian Oration (1902).

The Use of Instrumental Methods.

Up to recent times instrumental methods were mainly restricted to the laboratory and utilised for experimental researches upon animals. They are now largely employed in the clinical investigation of health and disease. The systematic examination of the urine for albumin and sugar, and still more the quantitative estimation of these substances and of urea, with microscopic examination of urinary and sputum deposits as clinical tests, are well within the time of many of us. The observations of Wunderlich, Ringer, and numerous others with the clinical thermometer have rendered exact the more crude recognition of the older physicians that the body temperature, so wondrously constant under all conditions and vicissitudes in health, is readily disturbed in definite ways by blood ferments and altered tissue metabolism in disease. It must be confessed that these instrumental aids have not always at first been received with the cordiality they deserved by clinical physicians. I can remember one of the pioneers of the clinical thermometer being somewhat petulantly snubbed by a very distinguished physician of that time on producing in a post-mortem room the temperature records characteristic of a case of tuberculosis.

Diseases of the circulatory system have been especially favoured by this combination of laboratory and clinical methods. Observations on the pulse—old as the history of medicine—have been supplemented by the refined methods of the sphygmograph. Again, such instruments as the capillary pressure gauge, the radiographic apparatus, the combined veno- and cardiograph and the electric cardiograph have given us, in association with the stethoscope, a comprehension of the cardiac mechanism and its perversions in disease which is almost complete. Greatly as we are indebted to laboratory investigation for exact knowledge and clinical insight, we must not forget how much has been and is being learned and suggested respecting vital processes by the older and less exact methods of clinical observation. Need I point to the laborious and minute clinical observations by Harvey himself, and his innumerable necropsies and dissections.

[17] Journal of Physiology, vol. xlvii., Nos. 4 and 5. THE LANCET, Feb. 14th, 1914, p. 469,

The Coördinating Control of Clinical Observation.

Whilst fully recognising and rejoicing in the value of instrumental aids we must be careful, then, not to weaken by disuse the coördinating control of clinical observation. The more deeply we study the human mechanism—and where shall we find a more profound lesson than may be drawn from the circulation and properties of the blood—the more we shall be convinced of the complete interrelation of its parts as they have become evolved from one comprehensive bioplasm. Instrumental methods deepen insight and observation at the bedside, whilst ever remaining in reserve for the more thorough investigation of individual cases of obscurity. Unless thus employed, however, in due perspective with the whole clinical phenomena of disease, any one method must prove full of the fallacies inherent in all isolated methods. I would urge, then, a steady maintenance in full efficiency of general clinical observation in correlation with all necessary laboratory and instrumental methods as essential to our right interpretation of disease; for it cannot be doubted that a want of coördination and perspective in the use of the two methods breeds bad physicians and tends to reckless and sometimes harmful treatment. In my humble opinion, Sir, and in this I agree with some previous orators, no institution of lectures has been more valuable to the profession and more in accordance with the spirit of Harvey than those founded by our distinguished Fellow, Dr. Oliver, in memory of the revered teacher of still some of us, Professor Sharpey. Clinical observation and teaching have been encouraged and the dignity of medicine enhanced by the able men who have given these lectures in successive years since 1904. We should never forget that the great physiologist and anatomist and Fellow of this College, whom we commemorate so proudly to-day, was also a great physician and an acute and laborious clinical observer.

(To be concluded.)

Belfast Medical School.—The work of the present winter session of the Medical School, Belfast, began at the University on Oct. 13th, when lectures were resumed, and at the Royal Victoria Hospital on Oct. 16th Dr. V. Fielden, the anæsthetist, gave an opening address to the students on "Suggestion or Psychotherapy," discussing the various views held in reference to that method of treatment. Senators, members of the teaching staff, graduates and undergraduates of the Queen's University were present at a great meeting held in the examination hall of the University on Oct. 21st, "To consider the call of duty in the present national exigency"

SHELL WOUNDS IN MODERN NAVAL WARFARE.[1]

By BRYAN PICK, M.R.C.S. Eng., L.R.C.P. Lond.,
STAFF SURGEON, ROYAL NAVY;
R. A. RANKINE, M.B., B.S. Lond.,
SURGEON, ROYAL NAVY;
AND
J. LAMBERT, M.A., M.D. Cantab., M.R.C.S. Eng.,
SURGEON, ROYAL NAVY.

As up to the time of writing most of the wounded from naval engagements have been landed at the Royal Naval Sick Quarters at Shotley we have thought that a brief account of modern shell wounds with a description of the adopted line of treatment might be of interest.

At the sinking of the *Königin Louise* the guns were 4-inch; shells common or lyddite. These shells are made of forged or cast steel with thin sides. The common shells are filled with gunpowder, while lyddite shells are filled with lyddite, which has picric acid as its chief constituent. In the Heligoland action the same were used with the addition of 6-inch and 12-pounder shells. The shells used by the Germans are probably made of forged or cast steel and filled with tri-nitro-toluene. This T.N.T. is nitrated toluene (C_7H_8) and is similar to lyddite.

The wounded received were the survivors from the *Königin Louise* on August 5th and those who were hurt in the action off Heligoland on August 26th. In the case of the former engagement some were admitted within 16 hours of receiving their wounds, but in some cases it was not until 36 hours had elapsed that it was possible to land them and admit them into hospital. All these patients, many of them badly wounded and suffering from compound fractures and other serious injuries, had been in the water for varying periods and had been rescued by whalers lowered from the attacking ships and subsequently transferred to one of the destroyers. Here they received such first aid as could be given them. These cases formed the first batch of wounded received; the remainder were taken on board the *Amphion* within a short time of receiving their wounds, but on the next day, after she struck a mine, they had to be transferred to a destroyer. In the action off Heligoland the wounded for the most part were transferred from their own ships to the *Fearless* for transport to hospital, and were received in from 24 to 30 hours after the action. Some had been in the water and some had been transferred from the destroyers to the bigger ship. In these actions destroyers and light cruisers were for the most part engaged. In the destroyers first-aid measures alone can be adopted, and even in light cruisers any radical surgery is performed with much difficulty owing to the excessive vibration when the ship is travelling at any speed. We mention these details to show the disabilities which the wounded in action have to put up with at the outset and just during the time that rest and methods for combating shock are most necessary. Accounts of military warfare in South Africa state that some of the patients probably owed their lives to the fact that they were left lying, after the application of a first-aid dressing, where they fell and were not immediately removed to the field hospital. In a naval action, however, this does not obtain, and it is frequently necessary to remove the wounded to a larger ship carrying a medical officer. Everyone knows the difficulty of getting into a small boat; add to this the possibility that a big sea is running and that the patient suffers from a badly shattered lower limb—it will be seen then that the patient's chances may be seriously handicapped by such necessary removal.

---

[1] Published by permission of the Medical Director-General of the Navy.

Before closing these brief general remarks we would point out the importance of early medical attention. All cases received first aid in some form or another; those patients received from the destroyers had had their wounds dressed and temporary splints applied. This first aid had been most efficiently carried out by those responsible, but the advantage of more skilled attention from a surgeon, had it been procurable, was plainly shown in one case—namely, that of a man with a badly shattered foot necessitating amputation later. In addition this patient had a deep wound of the muscles of the thigh; evidently there had been free hæmorrhage, for a tourniquet had been applied over the femoral artery, and at the time of admission of the patient this had been on for 36 hours. We mention this in no carping spirit, for the wounded owe a great deal in the way of comfort to the first aid they received. It is a further instance of the trials which they have to undergo. Those who had wounds which received early attention had less suppuration than had those in which it was given later. This was notably the case in those received from the *Fearless* after the engagement off Heligoland.

The Wound Caused by the Shell.

The shell on exploding bursts into pieces of varying size; the larger pieces probably cause more or less instant death. The wounds coming under observation were caused by pieces the largest of which measured about 3 inches by 1 inch. Probably the most severely wounded sank in the water. Wounds from shell come conveniently under the following headings:—

1. *No entrance or exit wound.*—Complete loss of superficial tissue.
2. *Wounds of entrance and exit.*—(*a*) When superficial, involving soft tissues, both wounds may be quite small or exit wound large. (*b*) When involving bone, comminution, and exit track contains fragments; exit wound large, ragged, and funnel-shaped.
3. *Entrance wound only.*—Metal found; if flat, wound is subcutaneous; if bullet-shaped, impacted against bone with fracture or embedded in deep tissues.

The above classification at the best is somewhat arbitrary and cannot include all cases.

Punctured wounds are common and may be caused by splinters. The large wound is generally lacerated, with contused margins. Much of the skin and superficial parts may be missing altogether. The surrounding skin and deeper parts may be seared and burnt. Many cases showed wounds of entrance and exit; some, wounds of entrance only. The shape of a piece of shell had some effect on the depth of the wound. If flat, the wound tended to be subcutaneous; if conical, it was likely to be deeply embedded. In the former class of wound we can call to mind two cases, both wounds of the back caused by large pieces of shell. From the entrance wound a long subcutaneous track ran, and at the bottom of this the piece of shell was found. In one of these cases a small external wound lay just over the shell, giving one the impression that the skin had split over the foreign body. The state of these wounds could easily be accounted for by the extremely sharp and irregular edges of the shell fragment.

Contents of Wound.

Shell may or may not be found. In most cases fragments of serge clothing were also present, and more rarely pieces of linen. In the *Königin Louise's* wounded, many of whom were wearing life-belts, numerous fragments of cork were found together with splinters of wood. When the bone was injured fragments of bone were usually found.

Effects on Special Structures.

(*a*) *Bone.*—For the most part bone is much comminuted and splintered; the fragments may be driven widely among the softer parts and through the exit wound and skin. In two cases—both compound fractures of the femur—there was an oblique fracture with little or no comminution. Whilst on the subject of fractures, one point in the examination of the wound seems worthy of mention—namely, the difficulty of deciding on probing as to whether metal or bone is felt. The old idea of a "ringing sound" appears somewhat fallacious. Possibly the shell is surrounded by fragments of clothing. The use of the finger is much more reliable.

(*b*) *Soft structures.*—Muscles, fasciæ, nerves, and blood-vessels may all be lacerated. Where muscle was affected there was a good deal of superficial necrosis. The condition of the main blood-vessels is of primary importance in deciding as to the necessity for amputation.

(*c*) *Special organs.*—Some cases brought in dead had abdominal injuries. Only one abdominal case came under treatment. This was a case of injury to the kidney which completely recovered. There was one case of depressed fracture of the frontal bone with subsequent subdural abscess caused by a very small splinter. Another case was one of spinal concussion with retention, and, later, incontinence of urine. In this case there was great comminution of the spinous processes and laminæ of the upper lumbar vertebræ, but no evidence of spinal compression. One case of surgical emphysema due to a wound of the apex of the right lung was admitted.

Shock.

In varying degrees this was present in almost all. Contributory causes were nervous excitement, loss of sleep, loss of blood, and the fact that many had been thrown into the water and subsequently rescued.

Hæmorrhage.

Primary.—Owing to the time that had elapsed since the engagements we saw none. Cases were brought in dead where large vessels, such as the femoral, had been severed.

Reactionary.—No cases of this were seen, as most of the patients were still suffering from shock with feeble heart beat.

Secondary.—During the time of the separation of the sloughs it occurred in varying stages, from a general oozing from the wound to bleeding from vessels the size of the thoracic axis and suprascapular arteries and the external saphenous vein. In one case a large abscess cavity was opened up and the bleeding vessel was found running through this with definite ulceration of the vessel wall.

Suppuration.

This occurred in practically every case. The skin, especially of the hands and feet, is grimed with dirt, oil, and coal dust, and stained with the fumes of cordite. Severe laceration of the parts, the entrance of shell, pieces of clothing, and other foreign bodies are contributory factors. As regards clothing, wounds into which serge entered invariably suppurated. In the case of linen the wounds were distinctly cleaner. In some cases shell was only found after the lapse of some weeks, the discovery being due to the formation of an abscess in a place some distance from the original wound. In one case in which the entrance wound was on the outer side of the thigh a hæmatoma developed below the gluteal fold and suppurated some six weeks later. This was opened and a large piece of shell and serge clothing were found in the neighbourhood of the tuber ischii about eight inches from the original wound.

Treatment.

Immediately on arrival a rapid survey of each patient was made. Later a more detailed examination took place and a line of treatment decided on. Cases with severe shock were treated on the usual lines, and no active surgical interference was carried out until signs of primary shock had disappeared. Those requiring immediate operation were found to be a comparatively small percentage. Conservatism in treatment has been the main principle. Even very severe lacerations of limbs were not treated by immediate amputation if the blood-supply was good. As long as the patient was not going down-hill from the condition of his wounds local treatment was persisted in. As an illustration we may instance the case of one who in addition to other serious wounds had a good half of the sole of his foot blown away. On admission what remained was covered by a gangrenous slough. This separated and exposed the metatarsals. However, the wound took on a healthy appearance, and when he left us showed signs of ultimately healing.

Primary examination was made by the X rays. Often, although splinters of shell could be seen, some difficulty was experienced in finding them at the time of operation, especially when embedded in the deeper muscles. Generally the patient was anæsthetised, the wound cleaned, foreign bodies removed, and the wound swabbed with iodine. Suturing of torn muscles and as far as possible approximation of the edges of skin were carried out with the idea of making the wound small. Drainage was generally necessary. In the case of fractures loose fragments were removed; those still attached to periosteum were left, being replaced in position. No attempt at operations such as wiring was carried out in view of the almost inevitable suppuration. Limbs were immobilised in splints, but the subsequent dressing of suppurating wounds greatly handicapped the union of these fractures. For these wounds we found peroxide of hydrogen to be our sheet anchor. It was used in 10 or 20 volumes solution, and was of the utmost value. The usual dressings were sterilised gauze and occasionally fomentations.

Vaccine treatment.—A series of cases were treated with the antisepsis vaccine of Parke, Davis, and Co. in the following doses of ten-fold diluted vaccine—daily doses of 3, 4, 5, 8, 10, 15 minims and 1 c.c.; then injection of 2 minims of undiluted vaccine every three days. (1 c.c. of undiluted vaccine contains 25,000,000 streptococci and 500,000,000 staphylococci.) The cases thus treated showed distinct improvement in lowering of temperature and separation of sloughs more rapidly than in cases not so treated. In cases not under treatment with the vaccine a septic type of temperature continued for from 2 to 3 weeks. It was found in many cases impossible to remove the disintegrated serge except by slight scraping and syringing of the sinuses. Vigorous scraping and probing are contraindicated owing to the danger of causing suppuration in fresh planes. The removal of such débris caused rapid cessation of foul discharge and consequent fall in temperature.

Conclusion.

Owing to local conditions we have been unable to see many of our cases through to the end. For the most part on leaving us the wounds were healthy and only required skin-grafting for their complete cure. It may be that further surgical measures may be necessary for some cases of non-union of fractures. The gap which contained comminuted fragments still attached to periosteum was often one or two inches in length, so that early union of those fractures cannot be anticipated.

Notes of Cases.

Appended are notes on a few typical cases.

Case 1.—Lacerated and contused wound over clavicle; middle third of clavicle comminuted and much displaced. Punctured wounds over right carotid sheath and in right forearm. Fragments of clothing removed from clavicular wound and shell from forearm. Surgical emphysema over lower neck and upper chest for two or three days after admission due to wound of lung, the apex of which could be seen exposed at the bottom of the wound. Some suppuration; healing well.

Case 2.—Admitted with big lacerated wound involving quadriceps muscles of the thigh on anterior and outer aspect. Also a wound 4 inches by 3 inches, with complete destruction of soft parts of sole of left foot down to flexor tendons. Above left ankle two large wounds with compound comminuted fracture of the lower third of the fibula. The right little toe had been shot away at the metatarso-phalangeal joint. Many fragments of clothing, cork, and bone were removed; much sloughing of tendons and muscles with very offensive pus. On leaving hospital wounds much smaller, granulating well, and healing. Secondary hæmorrhage from the peroneal artery in wound above ankle; this was controlled by plugging and pressure.

Case 3.—Compound fracture of right radius and ulna—a large gaping wound with great laceration was present on the upper postero-external surface of forearm and showing complete comminution of the upper two inches of the ulna; radius fractured at the neck. The muscles were much lacerated, but the main arteries were intact. There were also three small incised wounds over the left frontal region of the skull—at the bottom of one there was a slightly depressed star fracture of the left frontal bone. The elbow wound became very septic, necessitating continuous arm baths, and eventually as the patient became semi-comatose amputation in the upper third of the arm was performed and the skull was trephined at the same time. The left frontal lobe was much lacerated by a piece of bone driven in, and the hæmatoma thus formed had begun to suppurate, giving rise to a subdural abscess with secondary cerebral œdema. Owing to the latter a cerebral hernia formed and drainage became difficult. The patient eventually died a fortnight later.

Case 4.—Admitted with a lacerated wound 7 inches long from the right supra-malar region through the lobe of the ear, ending in a deep cavity in the right suprascapular region. The incision severed the parotid gland and branches of the seventh nerve. A large flat piece of shell was removed from the cavity. There were numerous punctured wounds of the right chest, forearm, and hand; fracture of the bases of the second and third metacarpals had been caused through a punctured wound of the hand.

The incised wound was sewn up and a counter opening made for drainage of the cavity in the suprascapular region. Suppuration followed in places, but the final result was good.

CASE 5.—Incised wound 4 inches long across right cheek; smaller wound of right ear. Punctured wounds in front of right shoulder extending to axilla, and behind left shoulder extending to suprascapular fossa. Numerous superficial "splash" shell wounds over both arms, chest, abdomen, and legs. Compound comminuted fracture of proximal phalanx of left second toe. Many small angular pieces of shell were removed from the various wounds. Secondary hæmorrhage occurred about 12 days later from the suprascapular wound which was opened up; an ulcer was found in the wall of the suprascapular artery, giving rise to free hæmorrhage. The artery was tied and the patient rapidly recovered.

CASE 6.—Shell wound in right lumbar region, 2 inches by ¾ inch. A probe passed upwards and inwards for 1½ inches. Hæmaturia followed and lasted for 14 days. Shell could not be seen by X rays. Recovery.

CASE 7.—Oblique fracture of right femur in lower third; compound from a small punctured wound. Another punctured wound in the upper third of the thigh. Extension and Liston's splint used. Six weeks later a hæmatoma was noticed on posterior aspect of thigh; this was opened and found to be suppurating in its deeper part and a large piece of shell with serge clothing removed. Union incomplete on leaving hospital.

CASE 8.—Numerous punctured superficial wounds of scalp, face, arms, abdomen, and back. Deep punctured wound left great trochanter and left great toe, both containing shell. A large lacerated wound was found over upper lumbar vertebræ; this was opened up, and great comminution of the spinous processes and laminæ of the upper three lumbar vertebræ was found. Loose pieces of bone were removed and free drainage given; the spinal dura mater had not been punctured and no symptoms of pressure on the cord were present. Temporary retention of urine, followed by slight incontinence, rapidly disappeared.

CASE 9.—Incised wound 4 inches long on left side of chest exposing costal cartilages; also large superficial shell burn on right chest and incised wound of forehead. The incised wounds were cleaned and sewn up. Compound comminuted fracture of right tibia with large anterior lacerated wound; the tibia was broken into small fragments for 2 inches and the muscles of the anterior group were much lacerated. Loose fragments were removed and the wound cleaned up and partly sewn; progressing well, although still some sloughing of superficial muscles and fasciæ.

Royal Naval Sick Quarters, Shotley.

PYLORIC OBSTRUCTION IN INFANTS.

BY CHARLES H. MILLER, M.D. CANTAB.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, LONDON HOSPITAL; PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

AN apology is hardly needed for describing a series of cases of pyloric obstruction in infants. Although many cases have been described in late years by clinicians of experience there is as yet no settled plan of treatment. Further, certain clinicians whose views on the subject seemed to be established now show signs of modifying their views and even of changing them entirely. It is evident, then, that the subject has not yet ceased to be a suitable one for discussion and exchange of opinions. I do not propose to discuss the pathology and etiology of this condition but merely to describe briefly a series of cases in the hope that the description will justify certain inferences and add to our general knowledge of the subject.

It is said that the condition is more common in males, that the symptoms commonly begin in the second month, and that it is characterised by forcible vomiting, visible gastric peristalsis, wasting, constipation, and the presence of a palpable pyloric tumour. With regard to the last sign I am rather sceptical. I have felt a hard cylindrical tumour in certain cases, especially during gastric peristalsis. But it is impossible to palpate deeply in many cases, and in some cases of wasting with a lax abdominal wall I have felt a similar tumour. I regard the palpability of the pylorus rather as a sign of wasting than of pyloric hypertrophy.

CASE 1.—The patient was a female, aged 18 weeks. There were present vomiting, wasting, constipation for four weeks, and peristalsis was seen occasionally. The patient was treated by gastric lavage twice a day and later on alternate days. She lost weight for two weeks and then improved in all ways, gaining 7 oz. in 24 days. All was going well when the child, who came of an epileptic stock, had a series of fits and died in three hours.

At the post-mortem examination the capacity of the stomach was found to be enlarged. The stomach wall was hypertrophied and the pyloric aperture was narrowed so that nothing larger than a probe could be passed easily. Mucous membrane in linear folds. Muscle of pylorus greatly thickened so as to form a hard resistant ring occluding the pylorus.

In the above case the age of this patient was a remarkable feature. Another point of interest was that although the pylorus was almost occluded post mortem it had been possible for the patient to put on weight.

CASE 2.—A male, aged 4 weeks. Vomiting, wasting; constipation coming on gradually for 10 days; visible peristalsis. Treated by gastric lavage and pancreatised milk. Gained 3 oz. in four days. Then diarrhœa set in and the patient became collapsed and died rapidly.

The post-mortem examination revealed hypertrophy of the pyloric muscle, causing narrowing of the lumen.

CASE 3.—A female, aged 9 months. Sudden illness with vomiting. Brought to hospital next day in a collapsed state. Very violent gastric peristalsis visible. Death in a few hours.

Post mortem a hard piece of meat was found plugging up the pylorus.

This case is quoted to show that visible gastric peristalsis can occur very soon after the pylorus is obstructed.

CASE 4.—A male, aged 8 weeks. Had been ailing for three weeks with obstinate vomiting. He had improved and had gained weight for a time under small doses of tincture of opium and feeding with dry feeds of virol. The stomach had not been washed out. The patient began to "go down hill" and vomiting set in again. He was treated with gastric lavage and pancreatised milk. He improved for 24 hours as regarded vomiting, but it became worse again, causing sudden collapse and death two days after he was first seen.

CASE 5.—A male, aged 5 weeks. Vomiting, constipation, wasting, peristalsis. Treated with lavage and pancreatised milk. Improved steadily from the start. In two weeks increasing feeds of citrated milk were used to substitute pancreatised milk. Though visible peristalsis continued the improvement was maintained and the patient left the hospital in seven weeks. When seen some months later he was in good health.

CASE 6.—A female, aged 10 weeks. Similar condition to Case 5. In hospital seven weeks. Treatment and progress similar to Case 5. When seen later was in good health.

CASE 7.—A female, aged 14 weeks. Wasting, forcible vomiting, constipation, very violent peristalsis. Treated by gastric lavage and pancreatised milk to which albulactin was added later. Lost weight for the first four weeks and then gained steadily. The weights in October were 7 lb. 7 oz., 6 lb. 14 oz., 7 lb. 1 oz., and 7 lb. 2 oz.; in November 7 lb. 1 oz., 7 lb. 3 oz., 7 lb. 7 oz., and 7 lb. 13 oz.; in December 8 lb. 1 oz., 8 lb. 4 oz., 8 lb. 8 oz., and 8 lb. 14 oz.; in January 9 lb. 10 oz., 10 lb. 4 oz., and 11 lb. 6 oz. Lavage was gradually omitted; citrated milk feeds were gradually used to replace pancreatised milk. When seen at the age of 2 years the patient was a healthy, strong, well-developed child, never having any gastric trouble.

CASE 8.—A male, aged 11 weeks. Very violent peristalsis in which three distinct waves could be seen; forcible vomiting, wasting, constipation. Treatment similar to Case 7. Progress slow at first, and then rapid gain in weight. In hospital 11 weeks. The patient was in good health when seen six months later.

CASE 9.—A female, aged 6 weeks. Wasting, constipation, forcible vomiting; peristalsis occasionally seen. Treatment on the usual lines. Progress was at first in the wrong direction, 1 lb. in weight being lost in the first month. After the first month there was a steady gain in weight. Weights: July, 8 lb. 8 oz.; August, 7 lb. 9 oz.; September, 8 lb. 7 oz.; October, 8 lb. 13 oz.; November, 10 lb. 1 oz.; December, 11 lb. 1 oz.; January, 12 lb. 5 oz.; February, 14 lb. 10 oz. Reported two years later to be in good health.

CASE 10.—A female, aged 16 days. Still under observation at the age of 5 months. This patient has been the most troublesome of all. Her weight on admission was 5 lb., and at the age of 5 months 8 lb. 5 oz. For five weeks weight was gradually lost until the condition seemed desperate. Then an ounce was gained and a gradual gain took place with periods of slight loss or stationary weight. The child is now in a satisfactory condition and is developing steadily.

This patient is the youngest of the series. At first peristalsis was seen occasionally; it is still seen after feeding.

In examining the above series it will be seen that one case (Case 3) is not a case of pyloric stenosis but of obstruction of the pylorus by a foreign body.

Of the remaining nine cases the following points may be noted:—

Sex.—There are 5 females and 4 males.

Age.—The males are younger than the females, except in one instance. The earliest age was in a female, 16 days; the greatest age was in a female, 18 weeks; but the average age is younger in the male.

Result.—Of the 3 fatal cases, 2 were males and 1 female. One patient died from fits, another from diarrhœa, and a third was in a very bad way and died within 48 hours of first being seen. Of the 6 who recovered 5 have become perfectly normal children and have been kept under observation since. In some cases recovery was straightforward and rapid; in others the struggle for improvement was desperate, and only after many vicissitudes did the patient come out of it alive. The remaining one is Case 10, who is still under observation.

Physical signs.—1. Vomiting. This is one of the most characteristic features of the condition. It is sudden and forceful. The stomach contents are shot a long way, sometimes even out of the cot. 2. Wasting and constipation require no comment. 3. Peristalsis is a variable sign. It is sometimes very definite as in Cases 7 and 8. In other cases —e.g., Cases 1 and 9—it is only seen occasionally. In Case 1 there is no doubt about the pyloric stenosis as there was a post-mortem examination. It is perhaps unjustifiable to draw conclusions from a limited number of cases; but in these few cases it was noteworthy that if peristalsis was violent the treatment was much easier and progress steadier. In the cases in which peristalsis was not an outstanding feature the treatment was much more troublesome and the progress more uncertain. Case 3 proves that visible peristalsis may occur without there being any hypertrophy of the stomach. Peristalsis should be regarded as a sign of obstruction rather than of hypertrophy. Peristalsis of the stomach is frequently seen in young babies who have vomiting, colic, and constipation. I have records of many such cases seen in out-patients and treated satisfactorily by castor oil and eliminating milk curd from the diet for a few days. These cases may be regarded as instances of "pyloric spasm." Possibly if they were untreated a hypertrophic stenosis might follow. Who knows? 4. I have already expressed my opinion on the palpable pyloric tumours.

Treatment.—The medical treatment of these cases requires the greatest care and skill on the part of the nurse. I wish to record my great indebtedness to Sister Louise, of the Victoria Hospital, to whose devotion the six successfully treated patients owe their lives. Of those who died, Case 2 died when she was on her holiday, Cases 3 and 4 were not under her care, and Case 1 died from fits while gaining weight satisfactorily; so that Sister Louise can claim that she has had 6 cases, all successful. The medical treatment consists in (1) keeping the patient warm; (2) washing out the stomach; and (3) feeding with predigested milk.

1. Keeping the patient warm seems easy, but with a very minute infant it is not so easy as it seems. I have found that the most satisfactory way is to put the baby, all but the head, in a hot-air bath that can easily be rigged up in an ordinary cot. A fracture cradle is taken and draped with pieces of blanket. Inside it are hung an electric lamp and a thermometer. The air inside the cradle is thus warmed and kept warm.

2. Washing out the stomach requires little description. It can be done with the baby sitting up on the nurse's knee or lying down on one side. It may have to be done several times a day, but usually twice a day is often enough. After a week once a day is enough as a rule. My practice is to use warm tap-water, which is a moderately good solvent of mucus. Occasionally I use a solution of bicarbonate of soda or citrate of potash. I have given up the constant use of these solutions as a routine method, as I have found in several cases that, after a few days, there was a tendency to diarrhœa. If the child is too feeble to stand regular washings out warm water can be given to drink. A vomit will probably follow which may bring up some mucus.

3. Predigested milk will be for a long time the sole diet. I prefer liquor pancreaticus to other preparations for the purpose of digesting milk. The milk should at first be given a teaspoonful at a time every half hour. When this amount is tolerated the interval and quantity may be increased. When the patient is beginning to thrive I have found virol and albulactin useful as additional foods.

Drugs are occasionally useful. When there are much colicky writhing and abdominal tenderness I give tinct. opii ♏ ¼ or chlorodyne ♏ i. three times a day for two or three days. I have tried belladonna, but found it useless in this disease. The bowels have to be kept open. An occasional dose of castor oil followed by grey powder will often be sufficient. Petroleum emulsion is also useful. Phenolphthalein is perhaps the most satisfactory drug to use regularly.

The most vital question of all remains: Is this condition to be treated by the physician or the surgeon? Doubtless there is much to be said on both sides, but all will agree that the disease is one of the most "tricky" that we know and is of a very "special" character. Whether we advocate medicine or surgery, it will be admitted that much depends on who the physician is, more on who the surgeon is, and still more on who the nurse is. If surgical treatment is employed it does not mean that it is a substitute for medical treatment. The after-treatment of the infant who has been operated on is just as "ticklish" as the medical treatment throughout. At best surgical treatment shortens the duration of the illness, and as time is valuable there is much to be said for operation. On the other hand, risks are great in surgical treatment and results vary in a most startling fashion with different surgeons. I trust that I may say without giving offence that there are comparatively few surgeons in whose hands operative treatment is not attended by very grave risks. Personally, I am trying to keep an open mind with regard to treatment and am endeavouring to find some definite indication which will direct the line of treatment.

In some of the cases in this series the patients have been sent to me by surgeons as they were too ill to stand an operation. In some the condition seemed desperate, but they eventually recovered. I think then that in the very bad cases medical treatment only can be recommended. When such patients begin to improve and are strong enough to stand an operation a surgeon might give his opinion once more. But it seems too like tempting providence to interfere with a treatment that is satisfactory. If the condition remains stationary for long or begins to decline after an initial improvement a surgeon should certainly be called in. If a child is seen in the early days of the disease and the diagnosis is definite I should recommend surgical treatment provided that the child has plenty of strength. But unfortunately such children do not come under observation in the early days, a remark especially true of hospital practice.

In conclusion, I would summarise thus: 1. Some cases can only be treated by the physician. 2. Some cases would be better treated by the surgeon; but whether they are or not, medical treatment will be necessary. 3. Whether the treatment is medical or surgical, neither will be effective without the care of a specially skilled nurse.

Queen Anne-street, W.

PROGNOSIS IN CANCER OF THE TONGUE.

BY WILFRED TROTTER, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

I. *Prognosis as to Cure.*

ONE of the greatest embarrassments of the surgeon in dealing with cancer of the tongue is the difficulty of making reasonably sure in any given case as to whether a satisfactory result of treatment is or is not to be expected. It commonly happens that in a case which the surgeon is inclined to regard as favourable the tumour proves to be desperately malignant and recurs after an extensive excision, and it occasionally happens, though unfortunately less often, that a very serious looking case proves to be unexpectedly favourable. Mistakes in prognosis of the most painful kind are thus, if the surgeon is betrayed into giving an opinion, extremely likely to occur. Moreover, this capriciousness in the behaviour of cancer of the tongue is apt to discourage systematic and thorough methods of operation, for the surgeon is tempted to believe at times that his most careful extirpations are as likely to be followed by recurrence as the less scientific procedures of an earlier time. Most surgeons of any considerable experience in the disease must, for example, occasionally have had to do with a patient who, after the primary growth has been successfully removed, has refused to submit to the gland dissection in spite of all warnings, and yet has remained permanently free from further trouble. Such experiences cannot fail to be disturbing, especially if one remembers at the same time the cases in which extensive gland operations have totally failed in their purpose.

Not only, however, are the results of clinical work inconsistent with one another, but they are also, at any rate ostensibly, irreconcilable with pathological findings. It has been conclusively shown by Cheatle in his histological studies that in many cases of cancer of the tongue, not necessarily of an advanced type, cancer cells can be demonstrated throughout the tongue muscles as far as their origin from the hyoid bone. And yet it has been demonstrated equally conclusively in actual practice that many operations which fall far short of removing the tongue muscles down to the hyoid are perfectly satisfactory in preventing local recurrence. It is true that in some such cases no doubt a true local recurrence in the muscles close to the hyoid bone has been mistaken for a glandular recurrence. With all due allowance for this fallacy, however, it remains the fact that those who have practised an operation which makes no pretence to attain complete removal of the muscles (Whitehead, Butlin) have been able to show results which are, to say the least, not grossly inferior to those of surgeons who regularly use a much more extensive procedure.

It seems to me that these difficulties of prognosis are very well worthy of discussion. It cannot be supposed that cancer of the tongue is inherently capricious in a way that must remain incapable of analysis, or that between two apparently similar cases, one of which defies an extensive operation while the other yields to a comparatively trivial one, there is no real and discernible difference of type. Apart from its theoretical interest the question is of considerable practical importance, for there can be no doubt that one of the reasons why the public still to a considerable extent refuses to submit to really early treatment of cancer of the tongue is the inability of the surgeon to give in *any case, however early*, a reasonably certain assurance that a cure will be attained.

The "Superficial" Stage of Epithelioma.

The majority of epitheliomata pass through a period in their early stages—lasting, perhaps, for about three months on an average—when the growth is strictly localised and unaccompanied by any infiltration of the tissues beyond its clearly palpable margin. The tumour then feels like a hard disc superficially embedded in the tongue and projecting above its surface. The amount of projection is considerable in proportion to the bulk which lies below the general surface. The tumour feels hard, and owing to the absence of surrounding infiltration the contrast between its consistence and that of the adjacent tongue is very abrupt. The size of the tumour may be considerable, and yet these characters be retained. Large tumours of this type always project markedly in a cauliflower-like mass.

A growth in this superficial period if removed with a margin of palpably healthy tissue ½ to ¾ inch wide is practically certain not to recur. If therefore the characters just given can be clearly made out and an adequate operation is done the surgeon is justified in giving a very definitely favourable prognosis as to local recurrence. I have never seen such a case in which after a suitable operation local recurrence took place.

It is most important to recognise that the fact that a given tumour is in the superficial period of its growth has no bearing whatever on the question whether glandular infection has occurred or not. It should be accepted as an incontestable principle in the surgery of epithelioma that as soon as the diagnosis of the primary tumour can be made the presence of glandular infection must be assumed. Nevertheless, when glandular enlargement is palpably present it shows varieties corresponding in prognosis with the superficial (early) and diffuse (late) types of the primary growth. Some surgeons are inclined always to give a very grave prognosis when enlarged glands are present in cancer of the tongue. My own experience by no means confirms this attitude. Provided the glands show clinical characters similar to those of the superficial type of growth—that is to say, are hard and well defined, and free from any trace of inflammatory manifestations—their presence if a thorough operation be done can scarcely be regarded as making the prognosis worse than if none could be felt. Even the number of the glands to be felt is comparatively unimportant and is certainly of much less significance than the signs presented by the individual glands.

It seems certain that the maintenance of the superficial stage of the growth is the result of the energetic and to a certain extent successful resistance of the tissues of the body to invasion by the cancer. We may suppose that outlying cancer cells penetrating the tissues are rapidly destroyed, and that it is only the compact mass of the whole growth which can maintain itself and advance successfully. Such a state of affairs will produce the well-defined frontier between cancer and surrounding tissue which is characteristic of the condition clinically and will explain why removal of the tumour with a comparatively limited margin is successful in eradicating the disease. Similarly is to be explained the clinical fact that the greater the proportion of the bulk of a tumour which projects above the surrounding surface the less its local malignancy tends to be—in other words, that the papillary and cauliflower growths are less malignant than the ulcerous and nodular forms. From the point of view of the nourishment of a cancer it is clear that infiltration of the tissues is the most advantageous mode of growth. If, however, this is prevented by a high resistance of the body tissues, a large part of the growth of the tumour must result in external projection—a less advantageous method of progress, since it is sooner or later limited by failure in blood-supply, as is shown by the well-known tendency of all largely projecting tumours to slough.

The "Diffuse" Stage of Epithelioma.

Sooner or later in their course all epitheliomata undergo a change in their mode of progress which is manifested clinically by signs which, although not always conspicuous, are usually perceptible to careful observation. The most important sign is a loss of distinctness in the outline of the tumour. The boundary between the cancer and the surrounding tissue is no longer the hard, sharp line of the superficial stage, but is obscured by an induration which fades gradually into the tongue. This diffuseness in outline may be very evident or only very slightly marked, but the detection of it is always extremely important. At the same time there may be a little œdema about the tumour and sometimes increased pain and tenderness, while the tumour itself tends to appear less hard.

I have elsewhere referred to this change as the onset of submucous invasion. It bears no necessary relation to the size of the tumour, so that a comparatively small tumour may show it quite clearly, but it is of the gravest significance in prognosis. The type of operation which is perfectly adequate during the superficial stage is now no longer of the least use, and whatever operation is done a favourable prognosis can no longer be given with any degree of confidence. It is of great importance to recognise that quite small tumours may be of this type, and that certain cases occur in which the tumour is of this type from the first. The classical three varieties of early cancer of the tongue—the papillary, the ulcerous, and the nodular—include one, the nodular, which shows typically this precocious submucous invasion. Epitheliomata of the posterior third of the tongue and of the sublingual fold are apt to be of the same type, and with the nodular form of cancer of the anterior part constitute a group of infamous reputation as regards malignancy.

A similar stage in the development of the disease in the glands also occurs. As with the primary growth all cases show it sooner or later, and some cases show it from the first appearance of gland involvement. The glands are then ill-defined and rather soft, so that they are not always very distinctly palpable. A gland of this type is the worst possible manifestation that can be found in an early case; a single one, perhaps not an inch in diameter, is of much graver significance than a dozen of the well-defined hard variety. Later such glands are apt to be accompanied by œdema and diffuse brawny induration, possibly with redness of the skin. Such a case is very likely to be mistaken for an inflammatory lesion by the inexperienced and treated accordingly.

It is probable that the diffuse variety of the disease in the primary growth is always associated with the same form in the glands; it is certain that they usually go together.

The precocious development of early diffuse invasion seems particularly liable to occur in strong, healthy, well-nourished subjects of florid appearance and comparatively early age.

Experience shows that operations undertaken for epithelioma in which the diffuse stage has begun are particularly apt to be followed by early, rapidly growing, and diffuse recurrence even when the type of the disease has been recognised, the growth is quite small, and the excision has been very extensive. It cannot be doubted, therefore, that in these cases there is a diffusion of cancer cells throughout the tissues around the growth to a distance far beyond the palpable induration and extending into regions which do not display the least abnormality to the naked eye.

When, therefore, operations are undertaken for this type of the disease there is no chance of cure unless an extremely drastic procedure is adopted. A radical extirpation of the tongue muscles down to and perhaps including the great cornu and body of the hyoid bone at the least on the affected side is essential, and there is a good deal to be said for total extirpation of the tongue and hyoid bone. The ordinary forms of excision of the tongue without total removal of the affected muscles including their origin, is a mere mutilation without any sufficient prospect of cure to justify it.

The pathological conclusion to be drawn from the clinical behaviour of diffuse epithelioma seems to be that in such cases the resistance of the body to invasion by the cancer has broken down, with the result that outlying cancer cells readily invade the tissues and survive and thrive at great distances from the mass of the tumour. The frontier between the cancer and the body is no longer defended and therefore ceases to be sharply marked. Invading outposts of cancer cells are no longer cut off as soon as they attempt to cross the boundary, but readily penetrate beyond it, extorting with no effort abundant nourishment from the passive and unresisting territory in which they find themselves. Such are doubtless the cases in which Cheatle found cancer cells living and active scattered throughout the muscles of the tongue at great distances from the primary growth. As has been already pointed out, the primary growth may yet be comparatively small when this collapse of the body resistance occurs. Indeed, it is probable that the so-called nodular form of cancer of the tongue owes its peculiarities to attacking a subject in whom the normal resistance is absent from the first. These cases of nodular cancer present appearances fully consistent with this view. The tumour grows from the mucous membrane and is fixed to it, but practically its whole bulk lies within the substance of the tongue. Over the summit of the mass the mucous membrane may be a little elevated and always allows the whitish colour of the tumour to show through. But the surface may be quite intact, and ulceration may still be absent at a time when operative cure of the disease is almost hopeless.

The fact that gland involvement in epithelioma does not as such greatly worsen the prognosis if the glands are of the hard, well-defined type suggests that gland involvement is not a stage in the progress of the disease due to a diminution of body resistance, but that directly an epithelioma begins it is able to affect the glands. Doubtless the growth of the cancer within the glands is energetically resisted and many early colonies of cancer there are exterminated, but the path to the glands is open from the first. When recurrence takes place after dissection for glands of the ill-defined type it occurs not, as a rule, in other glands beyond the region which has been dealt with, but in the tissues surrounding the area of operation. The suggestion of this fact is that when a gland becomes ill-defined the change means that the tissues surrounding the gland have lost their resistance to invasion and are being attacked successfully by the glandular mass of cancer in exactly the same way as the tissues about the primary growth are being attacked; but apparently it does not mean that the resistance of the lymphoid tissue itself has broken down. That this latter resistance remains high for a long period and even to the end is shown by the successful results of gland dissections (for gland involvement of the well-defined type), although the enlarged glands are numerous or possibly even bilateral, and by the fact that patients dying from gland recurrence rarely show invasion of the mediastinum. It is not, then, the progress of epithelioma along the lymphatics which constitutes the great difficulty in dealing with gland involvement, but rather the tendency of the surrounding tissues to lose their resistance to invasion by the glandular mass.

That, however, a general loss of lymphoid resistance to cancer can and does occasionally occur is well supported by clinical evidence. In my own experience it is chiefly an event of very long standing and chronic cases in which a series of incomplete gland dissections has been done. After perhaps several years, during which the disease has apparently been kept in check by the removal of individual glands as they become enlarged, there is suddenly an outburst of glandular enlargement over a wide area, and possibly even the whole body. Even then the individual glands may show no great tendency to invade surrounding parts, so that the condition seems to be one of collapse of lymphoid resistance without collapse of general tissue resistance. The occurrence is comparatively rare, but is a striking warning against trifling with even the most benign-looking gland involvement by partial operations.

The considerations it is desired to draw attention to may be repeated here in summary form. An epithelioma grows by local invasion of the tissues and by invasion of the lymphatic system. In early cases of the ordinary type growth in both these directions is energetically resisted. Successful treatment depends on both these antagonistic forces —the tissue resistance and the lymphatic resistance —being strong. As a rule the lymphatic resistance remains high throughout and no generalised lymphatic invasion occurs. In all cases, however, and in some quite early, the tissue resistance breaks down, and then diffuse invasion occurs both from the primary growth and the glands. The nodular form of cancer of the tongue is an admirable example of very early loss of tissue resistance.

It is maintained that the occurrence of this collapse of tissue resistance can be recognised clinically, and that prognosis depends on whether it has occurred or not. Operations undertaken before this event need be of only moderate severity, and yield very satisfactory results. Operations undertaken after this event must be very extensive and often seriously mutilating, and yield even then much less satisfactory results.

The liability to gland involvement is present from the first and cannot be regarded as constituting a definite stage in the disease. It follows, therefore, that a gland operation must be undertaken in every case, and that involvement of glands, provided there is no evidence of diffuse invasion of the tissues around them, is not of very serious prognostic significance.

II. *Prognosis as to Operative Dangers.*

The only serious dangers of even the most extensive operations are those due to sepsis, and I shall therefore make no attempt to deal with any others. Sepsis takes two forms—infection of the lungs and infection of the wound. The former if at all severe leads to abscess formation and gangrene with an almost necessarily fatal result; the latter may lead to acute septicæmia or to a cellulitis extending diffusely in the neck with the risk of mediastinitis and of secondary hæmorrhage.

In operations for growths of moderate size on the anterior part of the tongue these complications are not usually the cause of any serious trouble. When, however, the floor of the mouth, the posterior (pharyngeal) part of the tongue, or the pharyngeal wall is implicated, the danger is considerable. It is sometimes forgotten that the surgery of the mouth and pharynx has benefited from the introduction of antiseptic surgery less than the surgery of any other part, and that the surgeon working there has to elaborate a system of precautions against sepsis, which will include many features quite strange to the routine of ordinary aseptic technique.

Lung Complications.

Pneumonia or gangrene of the lung, for the terms are practically synonymous in this connexion, is unquestionably always due to inhalation of septic material into the lungs. No doubt blood sucked into the trachea frequently acts as a vehicle for such septic material, but the importance of it in itself has probably been exaggerated. Pneumonia not very uncommonly will occur after a preliminary gland operation if this has been extensive and prolonged, and there has been a large foul growth present in the mouth. During such an operation there is almost always some difficulty in maintaining a satisfactory airway; this obstruction greatly increases the amount of aspiration at the upper laryngeal opening, and so encourages the inhalation of septic matter from the growth. In operations on the primary growth the risk is, of course, very much greater, because to the factor of increased aspiration through partial obstruction is added disturbance of the growth which encourages the dislodgement of septic material from its surface.

The best precaution, therefore, against lung infection is the abolition of the possibility of aspiration. Some surgeons effect this by intratracheal administration of the anæsthetic. To my mind the risk of conveying septic material into the trachea during the introduction of the tube is a serious objection, and in my own practice I invariably use tracheotomy or laryngotomy—the latter usually for mouth operations as distinct from pharyngeal—followed by plugging of the pharynx. The little operation is quickly done and free from any risk of its own. In addition to its advantages in the control of pulmonary infection it has another which to my mind is almost as important. By rendering the breathing easy and effortless throughout it greatly diminishes the exhaustion of the patient. There can be little doubt that a long period of stormy, difficult respiration, chequered by intervals of struggling and coughing, is a very serious strain on the patient's strength. Such an experience is far from uncommon if it is attempted to do any of the more elaborate operations without means which allow of uniform quiet anæsthesia. For these reasons I regard the preliminary laryngotomy or tracheotomy as the one essential precaution in diminishing the danger of lung infections after operations for cancer of the tongue.

Local Infection of the Wound.

There can be little doubt that in ordinary cases of cancer of the tongue in which the growth is in the superficial stage local infection is a matter which concerns the patient's comfort and rapidity of convalescence more than it does his life. In such cases it can usually be prevented by adequate suture of the wound. It may seem to some, therefore, that in laying as much stress on it as I propose to do I am making too much of an inconsiderable matter. When we come, however, to operations for growths with deeply ulcerated surfaces and seated far back the dangers of local infection of the wound are admittedly very real. It is, of course, in operations of any extent upon the pharynx that this particular group of risks reaches its acme, and it is here, therefore, that the pathological conditions concerned and the prevention of them can be studied under most instructive conditions.

To a superficial examination the occurrence of grave conditions of local sepsis after operations has the same freakish character as has the attainment of cure of the disease. Similar seeming cases pursue a widely different course; one, perhaps, in which sepsis was not seriously feared develops extensive cellulitis, while another which seemed less favourable heals without causing serious anxiety.

A considerable experience of the surgery of the mouth and pharynx was necessary before even it became clear that the one thing that determines the occurrence or otherwise of grave local sepsis is the condition of the mouth. Operative technique, no doubt, can do much in limiting and controlling infection, but of itself it can give no complete safety. If the contents of the mouth have their ordinary virulent infectivity the most elaborate precautions and the most careful plastic protection of the wound may be brought to nought by uncontrollable sloughing inflammations. Ordinary cleansing of the mouth, scaling of teeth, removal of stumps, use of antiseptic washes with brush and dental silk make very little difference to the risk when carried out as a preliminary to operation. Moreover, patients with clean mouths and who are habitually careful with them are little if at all less liable to serious complications than those who are careless and whose mouths are obviously septic. I confess that this destruction of a time-honoured belief was a surprise to me, but it is also an admirable instance of the fact that the local pathology of the upper alimentary tract has many striking peculiarities.

On the other hand, *edentulous patients give rise to no serious anxiety on the score of sepsis.* I have never met with any exception to this rule, and I regard it as of the utmost value in forming a prognosis as to any proposed operation. It may be remarked also that in edentulous patients ulceration of the growth is much less and a much slower process than in those who still have teeth.

Supposing these were all the facts the solution of the problem would be very simple. It would merely be necessary to extract all the teeth present and then proceed to do the operation when the gums were healed. This is doubtless a drastic proposition, but I am quite sure that very few patients over 50, if the case were fairly put to them, would refuse their consent, especially if we could thereby guarantee a great reduction in the danger of the operation. I have put this proposal into practice, and while I have never had the least difficulty in obtaining the patient's consent to get rid of his remaining teeth, of which he is usually by now heartily tired, I have been a good deal disappointed by getting a great deal more sepsis than I expected.

It is clear, therefore, that there is a difference between the infectivity of the mouth of those who have recently lost their teeth and those who have been edentulous for a considerable time, so that we may conclude that some time must elapse between the extraction of the teeth and the operation. I am inclined to put this period in the neighbourhood of a month at the least. So great is the advantage to be expected that I am now willing to allow the growth to progress for that time, knowing that one's freedom in dealing with it and the diminution in danger quite compensate for the dangers of the delay. Moreover, I am inclined to doubt if the lapse of a month will ever convert a curable growth into an incurable one. It seems, therefore, that the intractable sloughing inflammations caused by contact with the oral secretions are due to an organism which is the invariable companion of the teeth, that its presence is independent of whether the teeth or gums are obviously infected or not, and that following upon removal of the teeth it does not disappear from the mouth for some time after the gums have healed.

The practical consequences of these considerations are obvious enough. In the first place, a favourable prognosis as to the danger of the operation can always be given in the case of edentulous patients. Secondly, a powerful argument is furnished in favour of the opinion that as soon as people come to the age when the teeth begin rapidly to give more and more trouble—say about 50, which is also about the age at which malignant disease of the upper alimentary tract is at its commonest—total extraction is a much more reasonable procedure than the most skilful efforts of plastic dental surgery. From the point of view solely of one who has to deal with a number of cases of cancer of the mouth and pharynx one would say deliberately that if a man develops cancer in this region the possession of natural teeth is a misfortune almost as great as the malignant disease itself. Thirdly, it becomes a duty when a suspicion of the development of malignant disease occurs to lose no time in dealing radically with the teeth so as to allow as long an interval as possible for the mouth to recover before the operation. As I have already said, most patients at the age of 50 are glad enough to part with their remaining teeth if this course is firmly and reasonably advised. At this time of life the teeth are almost certainly becoming increasingly troublesome, and efforts to preserve them increasingly difficult and unsatisfactory. Greatly as one must admire the achievements of modern conservative dentistry one cannot help feeling that when the teeth can obviously last but very few years, these hard-won triumphs might very well be reserved for patients of a younger age in whom vanity is a stronger or at any rate a more respectable passion.

Harley-street, W.

TUBERCULOSIS OFFICER FOR ROSS-SHIRE.—At a meeting of the Ross-shire county council held on Oct. 15th it was unanimously decided to appoint a tuberculosis officer for the county at a salary of £500 per annum. It was also decided by a large majority to defer preparing a scheme for a central hospital for the treatment of tuberculosis until the new officer had had time to investigate and form an opinion as to which would be the better, a central hospital or small district hospitals.

UNIVERSITY OF ABERDEEN: OPENING OF WINTER SESSION.—The winter session in the faculties of medicine and science in the University of Aberdeen opened on Oct. 16th, when Professor Theodore Shennan delivered the introductory lecture from the chair of pathology and Professor F. Soddy delivered the introductory lecture from the chair of chemistry. Dr. John Parlane Kinloch also gave his first lecture in public health. Principal George Adam Smith was present at all the lectures and introduced the new teachers. Before welcoming Professor Shennan the Principal paid a tribute of respect and affection to his predecessor, Professor G. Dean, and in introducing Professor Soddy the Principal alluded to the ability and devotion with which Professor F. R. Japp had filled the chair of chemistry, to which Professor Soddy was now appointed, for 24 years, earning for himself in his retirement the cordial gratitude and esteem of the University. With regard to the new lectureship in public health, the Principal in welcoming Dr. Kinloch said that this lectureship was long overdue, and to-day they were congratulating themselves that it had at last been realised. On behalf of Professor Matthew Hay he expressed regret at his unavoidable absence.

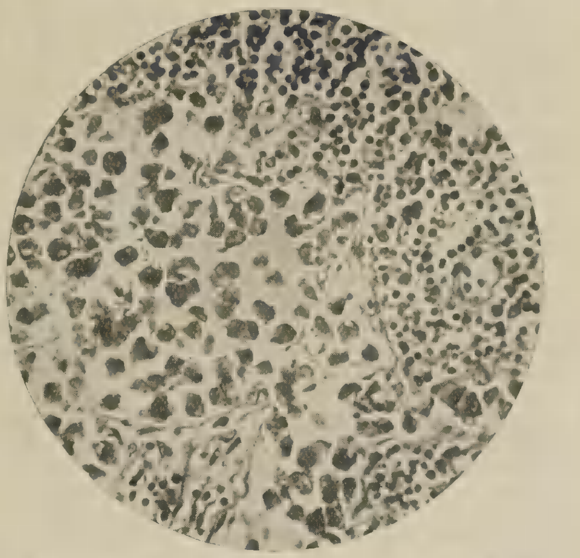
◆

A CASE OF MALIGNANT DISEASE OF THE LUNG.

By HUGH N. TAYLOR, M.A. CANTAB., M.D. DUB., F.R.C.S. EDIN.,
SURGEON, EBBW VALE HOSPITAL, MONMOUTHSHIRE.

ON July 3rd I was asked to see in consultation a man, aged 38 years, who was said to be suffering from a pleuritic effusion, probably of a purulent nature, subsequent to an attack of pneumonia. I found an emaciated patient with the left chest full of fluid. He had a slight hacking cough occasionally, and there was a history of some six weeks' "illness," but no definite account of any pneumonia. The patient was said to have several times expectorated "blood." There was no rise in temperature, and the pulse, which was feeble, was some 84 to the minute. But the man was evidently very ill, and I urged that he should come into the hospital, to which he was admitted the next day. When I saw him he had considerable dyspnœa but no pain. On aspiration—the first and only one—nearly six pints of fluid, deeply stained with blood, were withdrawn, but the dyspnœa was in no way relieved; in fact, the patient said that his "breathing was worse." There were some faint breath sounds after the tapping, but nothing very definite could be made out; no glandular enlargements could be felt. On two occasions he expectorated a small "currant jelly" mass. I formed the opinion that the case was probably one of malignant disease of the lung. The patient rapidly became weaker and died on July 12th, a week after admission.



Reproduction of a photo-micrograph showing endothelial cells invading lymphoid tissue. (× 300 diameters.)

As only a very limited post-mortem examination was allowed I could do no more than remove the left lung, which I found infiltrated at the root with a soft reddish growth; a mass of the same material was present on the surface of the lung in the submammary region, where it had become adherent to the chest wall. I sent the lung to the Clinical Research Society and received the following report:—

> This lung shows infiltration by a malignant growth, especially at the root. The growth is composed of large cells enclosed in an alveolated manner in a very scanty stroma. Its actual nature is not quite certain, but it is either a soft carcinoma or an endothelioma. If it is a primary growth it is probably the latter.

The illustration shows endotheliomatous material infiltrating lymphoid tissue. It is said that serous effusions are more usual in the nodular forms—i.e., in those of a scirrhous or epitheliomatous type, while the soft carcinoma or the endothelioma is evidenced by signs of consolidation with subsequent breaking down. In this case, however, there was nothing of the hard type to be felt either in the growth itself or in any of the glandular tissue at the root, while the effusion was very copious and deeply stained with blood.

Ebbw Vale.

NOTE ON LIMITATION OF THE AFTER-PAIN OF QUININE INJECTIONS.

By A. G. Peter, M.B., Ch.B. Aberd.

A serious practical drawback to the intramuscular injection of quinine is the undoubted after-pain which a large number of people suffer at the injection site, whether it be given in the lumbar or the gluteal region. Patients, where they have any choice, naturally prefer a practitioner who has not the reputation of advocating this line of treatment, and so greatly do some people dread the after-pain of quinine injections that they will resort to every kind of subterfuge to avoid them.

Last year one of my patients, whom owing to a very severe attack of malaria I had to inject frequently during the acute stage, wrote to me three months afterwards to say that although he then felt extremely well he was still conscious of tenderness at the sites of injection, and this though the utmost care was observed in securing strict surgical cleanliness at the time of injection, and no visible inflammatory reaction could be noted afterwards.

With a view to limiting if not abolishing this after-pain, I tried the addition of various local anæsthetics—e.g., eucaine B and novocaine—to the amount of quinine bihydrochloride given, usually between 10 and 20 grains, but with indifferent success. I then tried the addition of the recently introduced quinine and urea hydrochloride tablets, and was gratified to find a conspicuous absence of any after-pain when this drug was used. By trial the smallest amount required to ensure comfort afterwards was found to be half a grain of quinine and urea hydrochloride compound.

I have now had several severe cases of malaria where it has been necessary to give repeated hypodermics of quinine, and so far I have had no complaints from patients of after-pain at the injection site, although one of them was a man who was very sensitive to it, as I had proved by previous injection of quinine alone. I accordingly would suggest a wider trial of this combination, as patients will much more readily submit to injection, if they can be assured that they will have nothing further to pain them than the initial stab of the needle.

The points which call for note in this matter are: 1. A half-grain tablet of quinine and urea hydrochloride appears to be sufficient to remove the after-pain of quinine injections. My supply was obtained from Messrs. Parke, Davis, and Co., but I understand they can be obtained from any of the well-known chemists. 2. One tablet is added to the amount of quinine to be given, about 2 c.c. of water are then added, and the boiled solution received into a sterile 2 c.c. syringe for injection. 3. The solution is equally efficacious when boiled, but in too concentrated solution is apt to block the needle if not given at once.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Exhibition of Cases and Specimens.—Making Intestinal Fistula after Operation upon the Abdomen.

A meeting of this section was held on Oct. 8th, Dr. W. S. A. Griffith being in the chair.

Dr. H. Russell Andrews recorded a case of Severe Bleeding after the Menopause due to Rupture of a Vein in the Endometrium. The patient was aged 49 years; her periods ceased in 1910; there was a severe flooding in May, 1911. On admission the patient was blanched and a tumour was found reaching to above the umbilicus; this was proved at operation to be a degenerating fibroid. The tumour did not bulge into the cavity of the uterus, but the latter was enlarged and two dilated veins were seen on the surface of the endometrium; one of these had an opening visible to the naked eye. When the uterus was squeezed blood oozed out of this opening. The opening was large enough to admit a piece of thick silkworm gut.

Dr. Arthur E. Giles and Dr. Cuthbert Lockyer showed a case of Pregnancy Occurring within the Ovary. The patient was aged 32 years. She consulted Dr. Giles for sterility. Six months previously a menstrual period had been missed, after which the monthly flow was resumed [illegible] usual. On examination Dr. Giles found a rounded swelling of the size of a duck's egg to the right of the uterus; this was diagnosed as an ectopic gestation. At the operation the tumour was found to belong to the right ovary. The corresponding tube and mesosalpinx were normal. With the aid of the epidiascope Dr. Lockyer demonstrated: (1) that the pregnancy sac was completely surrounded by a capsule of ovarian stroma; (2) the presence of a large amniotic sac in which no fœtus had been discovered; (3) large chorionic villi with their mesoblast undergoing mucoid degeneration; (4) calcareous deposits in the blood clot around the villi; (5) decidual reaction in the connective tissue of the medullary portion of the ovary; and (6) decidual reaction in the cortical substance of the ovary. No lutein lamina could be found investing the gestation sac. The case was one of true ovarian pregnancy in which the embryo had died and the amniotic sac had become dilated by hydramnios. There were no visible blood-vessels in the enlarged villi, but their degeneration and the presence of calcareous deposits on the blood clot suggested that the death of the ovum must have occurred some long time before the operation.

Dr. Giles showed slides prepared from a case of Chorion Epithelioma removed from a patient aged 50 years, accompanied by a report on the histological findings by Dr. Dudgeon and Mr. Gordon Ley.—Remarks were made by Dr. W. Blair Bell, Dr. Herbert R. Spencer, and Mr. Gordon Ley.

Mr. J. D. Malcolm showed a Fibromyoma Uteri complicated by diffuse simple papilloma of the interior of the uterus. Those members who examined the sections were of the unanimous opinion that the "papilloma" was [illegible] adenocarcinoma.

Mr. Donald W. Roy communicated a case of Puerperal Eclampsia, fatal, from rupture of a large subcapsular hæmatoma of the liver into the peritoneal cavity.

Mr. Malcolm read a paper on cases in which an Intestinal Fistula was made with a View to Facilitate

Recovery from Operation upon the Abdomen. He discussed the condition sometimes arising after an abdominal section in which the surgeon believed that if the patient's bowels would move recovery would follow, but if the bowels would not move the patient would die. The symptoms were usually attributed to a paralysis or a paresis of the intestine, and this, in turn, was commonly believed to be due to a septic peritonitis. Mr. Malcolm expressed the opinion that in many of these cases the cause of trouble was not a septic peritonitis, but that the symptoms were due in part to a feebleness of peristaltic force, in part to some more or less definite obstruction of the intestine, and that the conditions might be correctly described as one of acute intestinal stasis. He recalled the fact that when opium was given in full doses after every abdominal section most of the cases did well, but if no gases escaped from the anus the patient always died not later than the fifth day and a slight spreading peritonitis was found after death. If in one of these cases a second operation was performed in the hope of finding an obstruction early on the fourth day or sooner, but when the symptoms were well developed, there was never any sign of spreading peritonitis in a typical case. Moreover, sometimes, if no second operation was undertaken, a patient immensely distended and apparently moribund would, without apparent cause, begin to pass gases from the rectum and all the symptoms would be completely and rapidly resolved. It was argued that the peritonitis found after death, when death occurred, could not be the cause of the symptoms, and that it was a consequence of the mode of death. The effect of modern treatment by substituting stimulation of the bowel and rational feeding for continuous administration of opium and starvation was pointed out, and records of cases were given in support of these views. In three cases patients seemed certain to die from vomiting and distension respectively on the tenth, fifth, and fifth days after an abdominal section. A Paul's tube was therefore inserted into the small intestine in two cases and into the cæcum in the third, and immediate relief of all symptoms followed. In the first case the patient died 16 months after the operation from general tuberculous disease with the fistula still open. In the other two cases the fistula was closed by operation and recovery was complete. In these three cases the bowel below the fistula resumed its functions without further surgical treatment. In a fourth case under similar circumstances the second operation failed and the patient died. There was no post-mortem examination, but there was a focus of infection from which peritonitis might have started. Mr. Malcolm assisted at two other operations for the relief of distension five days after the primary operation and these proved fatal, one being certainly a case of septic peritonitis. In both these cases attempts to release adhesions were made. In Mr. Malcolm's fourth case there was intense pain over the site of a colon anastomosis and great distension on the third day after the operation when complete relief was given by inserting a Paul's tube into the cæcum. The fistula closed spontaneously when an ileosigmoidostomy was performed 16 days later. In two other cases a fistula was made in the course of an operation—once in the ileum, once in the cæcum—to keep the lower bowel quiet, with good results, the fistula being closed later by operation. The importance of not making a fistula unnecessarily was insisted upon, but the fact that this treatment would occasionally save a life that would otherwise be lost was shown by the records given. The making of a fistula for the relief of distension was not likely to be successful in a case of septic peritonitis. If an early diagnosis could be made in a strong patient an immediate release of adhesions might give the most satisfactory results, but after the third day, if the patient was weak and if there were many adhesions, an extensive operation would almost certainly prove fatal, whereas a simple formation of a fistula might bring about a cure.—The paper was discussed by Dr. W. W. H. TATE, Dr. HENRY BRIGGS, Dr. C. HUBERT ROBERTS, Dr. GILES, and Dr. MARY SCHARLIEB.

VACCINATION IN BRISTOL.—From July 1st to Dec. 31st, 1913, 4467 births were registered; of this number 1093 were successfully vaccinated and 763 had certificates of conscientious objections. Of the remainder many had removed to "places unknown," and a considerable number were "unaccounted for."

Reviews and Notices of Books.

The Practice of Surgery.

By RUSSELL J. HOWARD, M.S. Lond., F.R.C.S. Eng., Surgeon, Poplar Hospital; Assistant Surgeon, London Hospital; and Joint Lecturer on Surgery and Teacher of Operative Surgery, London Hospital Medical College. With 8 coloured plates and 523 illustrations in the text. London: Edward Arnold. 1914. Pp. 1227. Price 21*s.* net.

THERE are many text-books on surgery, and new examples make frequent appearance, many of which possess some feature which commends them to the student. It is not at all easy to write a perfect text-book of surgery for the student, for while it must contain all that the student needs for his examination, it is especially difficult to deal with the latest additions to surgery. The writer must be able to discriminate between the new points which are important and are likely to be permanent and those which are merely of temporary interest. Still more he has to take care that those personal opinions which every surgeon holds and which have not been widely accepted should not be allowed to obtrude themselves too prominently.

In spite of these great difficulties several excellent text-books of surgery have appeared within recent years, and after a careful examination we do not hesitate to include amongst them the work which lies before us. In the first place it is clear; the author has taken great care to make the descriptions such as may be easily understood even by junior students; this is of great importance, for it is far better for the student to have an explanation which he does not need than for him to fail to find an explanation which he requires. In the second place the work is adequately illustrated, also a matter of great importance, for many things are much more easily learnt by the eye than by a written description. The illustrations have been chosen judiciously; many have been taken from the rich stores of the museum of the London Hospital Medical College, and there are numerous photographs of patients which should be very informing to the student.

Altogether we have much enjoyed reading this book, and consider that it should take a high place among the surgical text-books used by students. Here and there are places in which some judicious alterations might be made for the second edition when the time comes for it to appear. For example, in the account of the operative treatment of inguinal hernia the descriptions of the various operations which are performed are far too brief to be understood by the average student, though they will be perfectly clear to the surgeon.

Serology of Nervous and Mental Diseases.

By D. M. KAPLAN, M.D., Director of Clinical and Research Laboratories of the Neurological Institute, New York City, &c. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 346. Price 15*s.* net.

WE own to regarding with some suspicion each new work that appears on the subject of serum treatment and diagnosis, but we can say at once that the book before us well justifies its existence. It is evidently written by one who is an expert in the subject with which he deals, and who therefore has words of counsel to give which are deserving of attention.

The work is arranged in four parts. The first deals with the technique of lumbar puncture, with the composition of the cerebro-spinal fluid in health and disease, and with the method of performing the complement-fixation test for syphilis associated with the name of Wassermann. The second part is devoted to the serology of diseases other than syphilis, and the third to nervous and mental affections due to that protean disorder. Finally, Part IV. describes in detail the administration of salvarsan and the effects which may follow its employment.

The author's attitude in relation to the subject dealt with is much to be commended. He points out that errors may occur in the practice of even the most careful and experienced worker, and that the laboratory specialist must be on his guard against making assertions arising out of his tests as to clinical conditions when all he should report is the actual result obtained. He should be content to report that the Wassermann reaction is positive, not that the patient is suffering from syphilis, and so forth. "Surtout point de zèle" in short. He holds that the direction of error in this test is towards an undue number of positive reactions. On the other hand, syphilis is not cured by one dose of salvarsan as was formerly hoped. Dr. Kaplan notes as remarkable the frequency of a positive Wassermann reaction in cases of sclerodermia and of Raynaud's disease as suggesting a possible connexion between these affections and syphilis.

The book is well written and interesting. It has a sufficient number of cuts and plates, without being over illustrated. One small lapse in diction we feel bound to protest against, and that is the use of "most" for "almost" ("most everyone," p. 51). We have noted the same vulgarism in other books of late, and hope that it is not going to creep into the language either of this country or of the United States.

Development and Anatomy of the Nasal Accessory Sinuses in Man.

By WARREN B. DAVIS, M.D., Corinna Borden Keen Research Fellow of Jefferson Medical College. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 172. Price 15*s.* net.

THE fact that much has been published and still more has been said about the adult anatomy, the diseases, and more particularly the surgical treatment of the diseases of the accessory sinuses of the nose is evidence of the differences in the views expressed. These differences in some measure may have arisen from insufficient attention being paid to the embryology and development of the sinuses. The publication of the research work by Dr. Davis into the "Development and Anatomy of the Nasal Accessory Sinuses in Man" is therefore a valuable addition to the literature of the subject. The book is a record of observations based on 290 lateral nasal walls, showing the various stages and types of development of the accessory sinus areas from the sixtieth day of fœtal life to advanced maturity.

The difficulty in conducting a research of this kind is that of obtaining the necessary material. The bodies of children between the ages of 2 and 16 years are seldom obtainable in the dissecting rooms of European institutions as well as in America. It was necessary, therefore, in order to complete such a series to develop a technique by which the accessory sinus areas could be removed *en masse* at the time of post-mortem examinations, and still allow reconstruction of the face without marked disfigurement. In one of the opening chapters the methods used in obtaining and preparing the specimens are described.

A feature of the book are the 57 separate plates. The illustrations are natural size, unless otherwise stated in the legends, and are from drawings very accurately made by Miss Dorothy Peters, who has evidently given the most careful attention to detail. The plates are well printed, and the legends whilst succinct are fully descriptive. No pains have been spared in the production of a monograph which will be of value to the expert as well as to the beginner desirous of placing his knowledge on a sure foundation.

Scrofulosis.

By Professor G. CORNET. Translated by J. E. BULLOCK, M.D. Brux., Assistant Medical Officer, the Eversfield Chest Hospital, St. Leonards-on-Sea. London: John Bale, Sons, and Danielsson, Limited. 1914. Pp. 515. Price 15*s.*

THE terms "scrofulosis" and "scrofula" have given rise to a considerable amount of confusion as regards their exact meaning. In the Hippocratic period χοίραδες was applied to the swollen glands in the neck which, forming a continuous outline with the lower jaw and shoulders, produce a resemblance to the full contour of the pig's neck. At the present time some observers consider scrofulosis to be a slowly progressing localised tuberculosis, others are of opinion that the condition is due to a certain disposition or dyscrasia, which in its course often presents tuberculous complications. In recent times changes in other organs have been more definitely taken into consideration, such as the skin, mucous membranes, and joints.

In the volume now before us an interesting and comprehensive survey of the whole subject is given, which, although obscure in some details, nevertheless presents the nature, diagnosis, and treatment of scrofulosis in a scientific manner. Dr. Cornet considers that in the sense now accepted scrofulosis comprises a complex of symptoms almost entirely confined to childhood and early youth. Such, he says, affect the skin and the various mucous membranes: lupus, scrofuloderma, lichen, tuberculides, eczema, impetigo, chronic blepharitis, and phlyctenules; others are middle-ear disease, chronic catarrh of the air passages, rhinitis, pharyngitis, bronchitis, hyperplasia of the tonsils, catarrh of the alimentary canals, and lastly, certain affections of the bones and joints. This list is a satisfactory one, and accurately cites the changes likely to be encountered. These processes are, of course, not of themselves specific of scrofulosis, but are distinguished from other non-scrofulous phenomena of a similar kind by their persistency, frequent recurrence, and multiplicity. Two forms of scrofulosis are distinguished: (1) the tuberculous form due to the tubercle bacillus; (2) a non-tuberculous form caused by other bacteria. We believe bacteriologists will agree with Dr. Cornet that these organisms are mostly the staphylococcus (aureus and albus) or the streptococcus. To these he adds (3) a combination of both processes, the tuberculous and the pyogenous, the mixed form of scrofulosis, the effects of which differ according as the tubercle bacillus or other germs come into play first or simultaneously.

The relationship of scrofulosis to tubercle bacilli of the bovine type is discussed at length, and Dr. Cornet's well-known observations on the modes of infection by the human, bovine, and avian types are again chronicled. He repeats the opinion that bovine bacilli are almost avirulent for adults and are only virulent for children to a modified degree, very seldom producing a pronounced tuberculosis. The symptomatology of the condition is well described, and the measures to be adopted in regard to prophylaxis are duly set forth. The principles of the therapeutics of scrofulosis are clearly laid down and many valuable suggestions are made. Amongst internal remedies iodine takes first place. Cod-liver oil is described as an auxiliary of nutrition rather than as a medicine.

The whole volume is full of interest, and demonstrates the large amount of labour involved in its production. A word of praise must be awarded to Dr. Bullock for the manner in which he has translated the work.

L'Appareil Thymo-Thyroïdien: Thyroïdes, Parathyroïdes, Thymus. Anatomie, Physiologie, Pathologie, Déductions Thérapeutiques.

Par L. LAUNOY, D.Sc., Assistant de Physiologie à l'Institut Pasteur. Paris: J. B. Baillière et Fils. 1914. Pp. 405. Price 14 francs.

THIS work deals with what the author calls the "thymo-thyroid apparatus," comprising three distinct, but anatomically closely related, organs. A careful description of the embryology, anatomy, physiology, and pathology of each organ is given. The descriptions will be of interest both to physiologists and comparative anatomists, because they deal with the great variety of form, position, and general relations of these organs in all classes of vertebrates. Besides collating and giving a résumé of the work of other observers the author gives the result of his own experiments. References are given to the newer literature, and in the text itself there are 50 illustrations.

Embryologically, all three organs have the same origin from the mesoderm, being derived from the epithelium of the branchial clefts; the thymus and parathyroid from the epithelium of the branchial pouches, which are, of course, saccular dilatations of the branchial region of the digestive tube. The author regards the evidence as sufficient to group all three organs under the title "thymo-thyroid apparatus." The parathyroids are absolutely essential for life, because their removal causes death sooner or later. So, also, is the thymus—at least, in young animals. The thyroids do not seem to be so immediately necessary to life. As regards the relation to tetany, the thymus stands next to the parathyroid, and the same appears to be true as regards the psychical factor. The effects of removal of the thymus—idiocy—should be compared with those that obtain after removal of the thyroids. These two organs seem to govern the metabolism of the calcium salts in the body. The loss of calcium after their removal is the necessary corollary of the acid intoxication or acidosis consecutive to the excision of each of these organs.

As to the thyro-parathyroid apparatus, the one cannot functionally replace the other. After their excision the thyroids are responsible for the myxœdema, the cutaneous trophic disturbances, the dementia and other well-known symptoms, while the parathyroids are responsible for the tetany. Removal of the thyroid causes a special cachexia, compatible with long life. It does not appear to be demonstrated that exophthalmic goitre is due to hyperthyroidism. At any rate, experimental hyperthyroidisation causes phenomena which are difficult to reconcile with those of Graves's disease. Removal of the thyroid is followed by hypertrophy of the hypophysis. Nor is it demonstrated that the iodised protein substances in the thyroid owe their specific action to the iodine they contain. All mammals develop tetany after removal of the parathyroids, and their complete removal is rapidly fatal. Birds—especially young specimens—are less sensitive than mammals to removal of the thyro-parathyroid couple. The tetany may supervene suddenly, as in the dog, cat, and rabbit, or only after many days—e.g., 30 days in the monkey. It may be more or less permanent if part of the parathyroid remain.

The thymus, though a transitory organ, never completely disappears. It is an organ very susceptible to all causes of infection. The X rays cause a permanent involution. Its removal causes a "cachexia thymopriva," slow but fatal. Is it an organ related to the formation of nucleins? It appears to be correlated functionally with the genital organs. In 80 per cent. of the cases of Graves's disease there has been found a persistent large thymus.

Such are the arguments and conclusions of this most useful monograph.

The Psychopathology of Everyday Life.

By Professor Dr. SIGMUND FREUD, LL.D. Authorised English edition, with Introduction, by A. A. BRILL, Ph.B., M.D., Chief of Clinic of Psychiatry, Columbia University, &c. London: T. Fisher Unwin. 1914. Pp. 342. Price 12*s.* 6*d.* net.

THE English translation of Professor Freud's book "Zur Psychopathologie des Alltagslebens" is made from the fourth German edition, which was reviewed in THE LANCET of Dec. 20th, 1913, p. 1776. It is not therefore necessary to go over the ground again, but reference may be made to one or two additional matters suggested by a re-reading of the book in its English garb.

The assertion is made by the author that the forgetting of names is conditioned, in general, by two considerations: either the name itself touches something unpleasant, or it is brought into connexion with other associations which are influenced by such effects. Various elaborate and complex instances are supplied to exemplify these assertions. It is curious, however, that the influence of interest is ignored or minimised, and also that the most obvious explanation of name-forgetting, as in the case, say, of a physician who sees hundreds of out-patients weekly, is not so much as mentioned. For a whole series of seemingly accidental awkward movements, again, we are assured that the correct explanation is that the movements are in reality skilful and designed. If we knock something off a table, we do it by design, never by accident. Professor Freud's words are: "I actually believe that we must accept this explanation." If we give a beggar or a cabman a half sovereign instead of a sixpence, "the solution of such mishandling is simple: it is an act of sacrifice designed to mollify fate, to avert evil, and so on." In place of the term "chance actions," Professor Freud would substitute "symptomatic actions," for they are said to give expression to something which the actor himself does not suspect in them.

For all these statements, and others even more far-fetched, we are assured that psycho-analysis furnishes the justification. In a word, the whole structure is based on the reliability of psycho-analysis as a method of investigation, and it stands or falls with it. Apart, therefore, from the inherent improbability of much that is herein offered as the sole possible explanation of trifling events, apart from the author's refusal to accept the plain and the obvious, and his penchant for the recondite and the subtle, he has staked his faith entirely on the trustworthiness of psycho-analysis as a means of discovering the secrets hidden, as he believes, in the recesses of the mind. The objections which have been formulated to the genuineness of the interpretations put on the data thus obtained apply therefore to many of the "conclusions" here advanced with all the assurance of dogma.

The Diagnosis and Treatment of Digestive Diseases: A Practical Treatise for Students and Practitioners.

By GEORGE M. NILES, M.D., Professor of Clinical Medicine, Atlanta Medical College, Georgia. London: Henry Kimpton. Pp. 597. Price 21*s.* net.

THE growth of specialisation has produced in the United States the "professor of gastro-enterology," and this volume is an admirable compendium of the latest knowledge and the most recent technique in the field.

The resources at our command for diagnosis in chronic diseases of the digestive tract, especially of malignant disease of the stomach, have increased enormously in the last few years, and the author's account of them, notably of the use of Roentgen rays after bismuth meals, and of rectal injection with sulphate of barium, shows not only a complete grasp of technique, but great judgment in estimation of difficulties and limitations. The account of recent X ray work is one of the best sections of the book, reviewing carefully the deductions in diagnosis drawn by Holzknecht, Jolasse, and others. It requires great experience to interpret properly the appearance of visceral skiagrams, even of the best technical quality, and many an expert would gain knowledge from these pages. Considerable space is rightly assigned to the manipulation of the stomach tube. Simple as this instrument is, there is frequently a prejudice against its use, due to faulty manipulation. Dr. Niles employs the Friedlieb method of irrigation with a simple funnel. The author's procedure for duodenal feeding is that of Max Einhorn, who originally developed it.

All the chapters on treatment appear to be full, judicious, and well arranged. The author is throughout so careful to acknowledge obligation to other workers in this field and to allow them proper credit, that we are surprised that a reference bibliography has not been appended. The style of writing is simple, precise, and yet readable. So excellent is the whole that it is permissible to criticise trifles. There is not, and there never could be, such a word as to "ptose." "Ptosis" (a falling) is a good Greek word, but it is derived from πίπτω, and the proper derivation would be to "pipt," which would repel most seekers after new technical words. Dr. Niles perhaps dismisses intestinal antiseptics too abruptly, apparently because he considers it impossible to render the intestinal tract "aseptic." But it is possible to lessen the degree of protein putrefaction, even in the large intestine, and many well-known drugs will aid its prevention.

The work is truly a practical treatise suitable not only for students and practitioners, but even for well-informed specialists.

LIBRARY TABLE.

A Surgical Handbook for the Use of Students, Practitioners, House Surgeons, and Dressers. By FRANCIS M. CAIRD, M.B. Edin., F.R.C.S. Edin., and CHARLES W. CATHCART, M.B. Edin., F.R.C.S. Eng. and Edin. Sixteenth edition, revised and enlarged. With 208 illustrations. London: Charles Griffin and Co., Limited. 1914. Pp. 364. Price 8*s.* 6*d.* net. —On many occasions we have expressed our appreciation of earlier editions of this valuable work, and we are glad to see this the latest issue. An examination of the book shows that many alterations have been made in it since the appearance of the fifteenth edition, especially in the sections dealing with anæsthesia, with the treatment of fractures, and with spinal caries. Many of the older diagrams have been withdrawn and have been replaced by new, so that evidently much has been done to bring the book up to date. Here and there are statements which may be open to discussion, but we bear willing testimony to the high standard which has been reached by this deservedly popular handbook.

Industrial Training, with Special Reference to the Conditions Prevailing in London. By N. B. DEARLE, M.A., Fellow of All Souls, Oxford; Shaw Research Student of the London School of Economics and Political Science, 1907–09. London: P. S. King and Co. 1914. Pp. 605. Price 10*s.* 6*d.* net.—Mr. Dearle has presented in a readable form the facts connected with industrial training, principally with regard to London, accompanied by suggestions for remedying defects to which he calls attention and general constructive criticism. Some day, no doubt in less troubled times than these, his work will be found useful by those interested in educational and social reform. Those who study it now will find in the conditions he describes striking evidence of the social mischief due to lack of organised and disciplined effort, and to the unwillingness of employers and employed to acquiesce in or to demand educational organisation for their own benefit. Mr. Dearle's work will be found interesting by those who wish for information as to conditions as they are in this country. It does not, however, pretend to describe in detail with a view to our instruction industrial training as exists elsewhere—in America, for example, or in that highly organised and industrially trained country with which we are now at war—and it is rather through comparison and the desire to emulate the achievements of others that we must improve ourselves eventually.

On the Effects of Volcanic Action in the Production of Epidemic Diseases in the Animal and in the Vegetable Creation, and in the Production of Hurricanes and Abnormal Atmospherical Vicissitudes. By H. J. JOHNSTON-LAVIS, M.D., D.Ch., M.R.C.S. Eng., L.S.A. Lond., F.G.S. London: John Bale, Sons, and Danielsson, Limited. 1914. Pp. 67. Price 3*s.* net.—This essay gained the Parkin prize of £100 awarded by the Royal College of Physicians of Edinburgh. It discusses the physics and chemistry of volcanic eruption and the physical effects of eruptions on human beings and animals. Pages 24–49 are taken up with a "small selection" of citations of different authors on the supposed relationship of eruptions to epidemic diseases of man, animals, and plants, and these are followed by a description of the physical effects of eruptions on plant life and the influence of eruptions in the production of hurricanes and abnormal atmospheric vicissitudes. The author concludes from the aseptic and antiseptic character of all volcanic materials, "with the exception of mud from the sea bottom, from crater lakes, or from the organic contaminated slope of the mountain," that there is no *direct* relationship between volcanic eruptions and disease in man or animals. He recognises and considers, however, the following indirect ways in which epidemic diseases may be related to volcanic outbursts: 1. Erosive effects of irritant and depressing fumes on the ocular, respiratory, and to some extent digestive, mucous membrane may lower resistance. 2. Watercourses may be disturbed or contaminated through landslips, and proper drainage may be interfered with. 3. The moral depression from fear may reduce resistance, as also may the imperfect nourishment consequent on the environment and conditions.

JOURNALS AND MAGAZINES.

Quarterly Journal of Microscopical Science. Edited by Sir RAY LANKESTER, K.C.B., with the coöperation of Professor SYDNEY J. HICKSON, Professor E. A. MINCHIN, Professor GILBERT C. BOURNE, and Professor J. GRAHAM KERR. Vol. LX., Part 3, September, 1914. London: J. and A. Churchill. Pp. 150. Price 10*s.*—The first article in the September number consists of Observations on the Gametogenesis of Grantia Compressa, by Mr. Arthur Dendy, professor of zoology in King's College, London. His attention began to be directed towards the problem of the origin of the germ-cells in calcareous sponges while writing a memoir on the common British species, Grantia compressa. In the course of this work it became evident that although the ova of this sponge were easily recognisable in the maternal tissues in various stages of growth, and also embryos in various stages of development, no one had ever been able to find the spermatozoa. In April, 1912, Professor Dendy accordingly paid a visit to the laboratory of the Marine Biological Association at Plymouth, and although unable to find spermatozoa in living specimens, he preserved material which on subsequent investigation furnished the clue to the solution of the problem. He found that the sponge was hermaphrodite, producing both male and female germ-cells simultaneously, but that the spermatozoa were produced in comparatively small numbers, the minute sperm-morulæ being scattered here and there, enclosed in spermatocysts, between the collared cells of the chamber walls, and also occurring free in the flagellate chambers. The spermatogonia in these sperm-morulæ were extremely minute, and nothing was ascertained with regard to their mode of division. Apparently they were sometimes transferred as sperm-morulæ to the inhalant canals of the same or of another individual. With regard to the process of oögenesis Professor Dendy has been able to give a fairly complete account of a number of very interesting stages. One of the most remarkable phenomena observed during his investigations was the nutrition of the growing oöcyte by means of phagocytic nurse cells.—In the second article Miss Monica Taylor discusses the chromosome complex of culex pipiens. For the purpose of this research she obtained very numerous pupæ of this gnat and placed them in small ponds which were covered over with large cages made of mosquito-netting, so that the resulting imagines could be observed. Her general conclusions are as follows: (1) the somatic number of chromosomes is three, both in the male and female of culex pipiens; (2) the number of chromosomes in the spermatogonia as well as in the primary and secondary spermatocytes and spermatids is three; (3) the spermatogonial cells are not characterised by a synizesis stage, which latter serves to mark off the spermatogonial from the secondary spermatocyte stage; (4) the nuclear membrane persists throughout mitosis; (5) the synizesis stage represents an inactive phase of the nucleus in spermatogenesis; and (6) a synizesis stage occurs in somatic nuclei.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

BOVININE.

(THE BOVININE CO., NEW YORK. LONDON AGENCY: W. EDWARDS AND SON, 157, QUEEN VICTORIA-STREET, LONDON, E.C.)

ACCORDING to our analysis there can be little doubt of the nutritive and tonic value of this preparation. Above all, it contains a directly assimilable albumin which is coagulated on heating. We found that the amount of coagulum yielded was no less than 14·85 per cent. This yielded on incineration mineral matter rich in iron. In the original fluid the iron occurs in the form of an organic compound. The spectroscope shows the distinctive bands given by hæmoglobin. The total solid matters amounted to 22·02 per cent. and the mineral matter to 1·44 per cent. The preparation keeps well, and to the preservatives used there can be no objection. They amount to a small proportion of alcohol and glycerine. In cases where a rapid nutritive and tonic are required bovinine seems well suited. Having regard to its special use for invalid purposes the price of it is consistent with its value.

DRAKENSTEIN WINE.

(E. WESTMACOTT AND CO., 368, STRAND, LONDON, W.C.)

This is a white wine produced from a Rhein stock in Cape Colony. It is a great improvement on the wines produced there some years ago. It is elegant, light, and agreeable to the palate, while possessing a distinctive flavour. For all practical purposes it is free from sugar, the actual amount present according to our analysis being 0·116 per cent. The total solid matters only amounted to 2·09 per cent. and the mineral salts to 0·16 per cent. It is free from excess of acid, the volatile acidity amounting only to 0·072 per cent., and the fixed acidity reckoned as tartaric acid to 0·525 per cent. The alcohol amounted to 13·43 per cent. by volume. The wine is well suited to dietetic purposes.

PLASMON OAT COCOA.

(INTERNATIONAL PLASMON, LIMITED, 66A, FARRINGDON-STREET, LONDON, E.C.)

This preparation shows a careful incorporation of the constituents indicated, and when prepared according to instructions gives a very palatable and highly nutritious food. In particular it is reinforced with the tissue-building material of milk. According to our analysis it contains just upon 20 per cent. of milk protein. In addition, there is 15·60 per cent. of fat present derived chiefly from cocoa. The moisture amounted to 6·50 per cent. and the mineral matters to 4·80 per cent. In these last there was an abundance of phosphates. It is a wholesome, sustaining food.

(1) BANANINA; AND (2) BARLEY FLOUR.

(BANANA BREAD FLOUR FOOD, LIMITED, CEREAL-COURT, 16, BRUNSWICK-STREET, LIVERPOOL.)

1. Bananina is an interesting product obtained by the drying and milling of banana fruit. It has the characteristic smell of the banana and is a fine flour which readily dissolves under the influence of the salivary and other ferments. The ripe banana contains an appreciable amount of sugar owing to the action of its own enzyme on the starch. Banana flour contains a small proportion of sugar inasmuch as it is prepared before the

fruit is fully ripe. We found present 2·40 per cent. of sugar. In addition to its energy value as a food banana flour supplies also some tissue-building material, since, according to our analysis, bananina contains 5·29 per cent. of protein (0·84 nitrogen). 2. We have examined also a specimen of barley flour which under the microscope presented the characteristic appearance of the genuine product. Barley shows less protein than occurs in wheat flour, but it contains more fat and it is richer in mineral constituents. The flour we examined was a genuine natural product, and there was no evidence of chemical treatment. In particular it yielded a yellow colouring matter to petrol, which shows that it has not been bleached.

VOCALZONE PREPARATIONS.

(MEGGESON AND CO., LIMITED, 14 AND 15, MILES-LANE, LONDON, E.C.)

These preparations attracted some attention at the medical exhibition held in Aberdeen in connexion with the last meeting of the British Medical Association. Their composition is based on the choice of well-known, harmless, and agreeable antiseptics put together in a menstruum which is attractive in application. Three preparations were submitted to us. The first was a clear green fluid, which is mentioned favourably in the treatment of coryza, nasal catarrh, and other secretory troubles in the nasal passages. It is a soothing, unirritating, cleansing fluid which can be used either as a douche or coarse spray. It has also been employed in diseases of the pharynx and larynx. Vocalzone gargle is composed of suitable antiseptics coupled with an astringent which makes it effective as a gargle. Lastly, vocalzone pastilles are designed to soothe irritable conditions of the throat and bronchial tubes. They are demulcent and sedative.

MAPLE SUGAR AND SYRUP.

(THE CANADIAN MAPLE PRODUCTS COMPANY, LIMITED, 1, ENDELL-STREET, LONDON, W.C.)

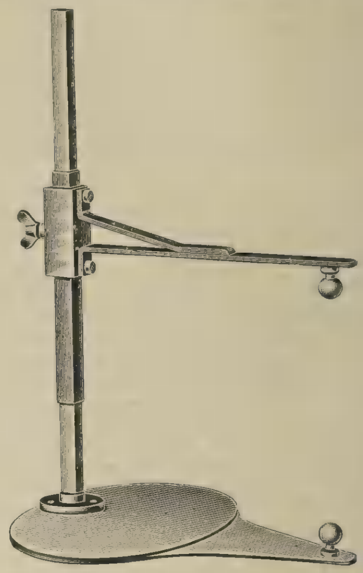
Maple sugar is chemically identical with cane or beet sugar. It has, however, a characteristic and to many persons an attractive flavour due to aromatic substances occurring in the bark of the tree. Maple sugar also is said to be slightly laxative. Apart from sweetness it has a quite interesting flavour, which is soon appreciated by those who have had no previous experience of it. Our analysis of the sugar was as follows: Moisture, 4·00 per cent.; mineral matter, 0·60 per cent.; invert sugar, 10·00 per cent.; and sucrose, 85·40 per cent. We also examined the syrup, which has to an even more marked degree the peculiar flavour of the sugar itself. We find that it is very susceptible to decomposition, for after a few days the syrup began to effervesce very rapidly due to alcoholic fermentation.

New Inventions.

AN AID TO THE RADIOGRAPHY OF THE PITUITARY FOSSA.

IN order to compare the size and appearance of the pituitary fossa in a series of radiograms it is obvious that the true lateral position of the skull must be chosen in each case. The axis of the tube must lie parallel to the plate and its target immediately beneath the fossa. This position of the head may be obtained: (*a*) by means of two metallic rings, one surrounding each external auditory meatus[1]; (*b*) by inserting a small coin into each of these apertures[2]; or (*c*) by placing a lead shot over the skin on each side of the head at the site of the sella turcica,[3] and subsequently manipulating the tube and the head until the image of one circle falls within the other, or until the two images of the coins and shot coincide. When shot are employed the target remains in the same position for the radiogram, but in the former devices (*a* and *b*) it is moved one inch towards the orbit and one inch towards the vertex of the skull.

As the time required for a good radiogram of the fossa may be as long as 30 seconds there is ample opportunity, especially in children, for slight movement of the head, the occurrence of which would prejudice the result. The simple instrument shown in the accompanying illustration (the model of which was constructed for me by Mr. Ilsley, electrician to the X ray and electrical departments of St. Bartholomew's Hospital) fixes and enables one to place the head in the desired position. It consists of a stand carrying a metallic bar, at the free end of which is fixed a leaden earpiece resembling that of a binaural stethoscope. Opposite to it, and fixed to the stand, is a second knob. The bar is movable upon the support and may be clamped at the proper height. The ear-knobs lie at the same distance from the pillar and in the same vertical line. Each fits into an auditory meatus. When inserted there is little or no tendency for the patient to alter the position. A piece of lead is then placed at the junction of the middle and outer third of a line running from the outer canthus of the eye to the external meatus, and the target is moved until it strikes the metal. The lead being removed, the diaphragm is opened and a radiogram taken. The determination of the true lateral position by means of radioscopy alone is uncertain and therefore inadequate for exact measurement.



The clip may be used when the tube is above and the plate beneath the head. Also it may be employed for stereoscopic radiograms of the fossa and orbit, for obtaining accurate lateral views of the face and the sinuses, &c. When the couch has a canvas top it may be preferable to lay upon it a rectangular piece of three-ply wood of suitable width for the support of the head. It may be provided with a spirit-level and with feet to raise the head an inch or more, taking care that the target remains the same distance in all cases. The head-clip is manufactured and listed by Mr. Leslie Miller, 66, Hatton-garden, London, E.C. It is obvious that the head may be fixed in a true antero-posterior position by the employment of the same principle and by the suitable modification of the instrument.

WALKER OVEREND, M.A., M.D. Oxon.,
Chief Assistant in the X Ray Department of St. Bartholomew's Hospital; Honorary Radiologist to the East Sussex Hospital, Hastings.

St. Leonards-on-Sea.

THE LANCET.

LONDON: SATURDAY, OCTOBER 24, 1914.

The Public Health Service and the National Crisis.

UNDER this title Dr. HERBERT JONES on Friday last, Oct. 16th, delivered the presidential address of the Society of Medical Officers of Health, and in spirited words indicated the part that has been played, that is now being played, and that will have to be played in the future by our public health service in securing for the British Empire the success that is necessary for its existence. For the magnitude of the struggle in which we are involved, and its deep significance both in the cause of justice and in the interests of national welfare, are now seen by all. With legitimate complacency Dr. HERBERT JONES pointed to the material upon which the country is now drawing to fill the ranks of the army as distinctly better than that upon which reliance had to be placed 20 years ago. At that time 40 per cent. of recruits were rejected on medical inspection; ten years later the percentage of rejections was reduced to 30; and now the discarded amount to but little over 20 per cent. of the total applicants, a good standard being maintained among the 700,000 young men who have recently joined the colours. A great share in the improved physique of the country is owing to our public health service, and this is our reason for returning so soon to a subject which we dealt with fully last week.

A large part of Dr. HERBERT JONES'S address was naturally occupied in explaining the relations now existent between the Territorial Army and the sanitary organisation of the country, and these relations show that we have learnt the lesson of the South African war, when more men were put out of action by preventable disease than by the bullets of our gallant friends who were then the enemy. At that time it was considered unnecessary to employ on the spot medical officers who had special knowledge of sanitary affairs. Upon the creation of the Territorial Force opportunity was taken to include in the new body provision for a sanitary service, and in 1907 Sir ALFRED KEOGH, then and now again, Director-General of the Army Medical Department, suggested that the medical officers of health of the country should combine in a voluntary organisation having for its object the preventive care of the masses of men who in the event of mobilisation would be required to prepare for the defence of the country. From this movement sprang the *à la suite* sanitary service, a well-conceived organisation, whose establishment, however, amounted to only 120 officers, and these had limited spheres of action. The want of flexibility to which the terms of the Regulations might have led has been remedied since, and we now know that wherever troops are stationed they will obtain the good offices of the medical officer of health of the locality. The Army Council has also indicated to the generals in command that the medical officer of health is in the best position to give information respecting both the existence of infectious diseases in any district and the drainage and water-supply to be found. To quote Dr. HERBERT JONES:—

> "With regard to the billeting of troops the medical officer of health is now to be communicated with before troops march into his district, with a view to obtaining his expert advice and coöperation in arranging the billets under the best sanitary conditions available. In the case of towns a telegram will be sent in advance to the medical officer of health appointing a time and place of meeting with the billeting officers, who are sent in advance to arrange for the housing of troops. In districts outside towns a telegram in similar terms will be sent to the medical officer of health of the county in which the troops are to be billeted. At Territorial Force Headquarters the medical officer of health will be consulted before men are furnished with billets, and where camps are formed and maintained he will be consulted and his visits encouraged."

That the medical officers of health of the country will rise to this great occasion and assist our military authorities with zeal and judgment no one who knows the thoroughness which has for so long marked their administrative work can for a moment doubt. But the duties which they have been instructed to take up, and which they have assumed with pride and alacrity, will call for great delicacy as well as complete thoroughness in execution. There are still among our military authorities those who are ready to suspect in non-military assistance undesirable interference in the higher spheres of the art of war, and such authorities will need to be approached circumspectly, but with full recognition that all parts of our fighting machine are equally alive to the paramount importance of securing the health of the troops.

The War and the Dislocation of Private Practice.

WE have already referred to the fact that the depletion of the staffs of the general hospitals of the country has all over the kingdom been very marked owing to the mobilisation of the Territorial Forces, and it is now recognised that the dislocation of private practice which has followed upon the same cause is becoming grave; indeed, if sickness should break out in many districts of the country the outcome would be truly serious. The Executive Committee of the General Medical Council has throughout paid anxious attention to this matter, and we are able to add that the

War Office is in full sympathy with the Council in any effort to prevent needless removal of a large body of medical men from their regular duties. We all recognise that at this moment military exigencies must come first: the General Medical Council feels this as clearly as every medical man. The machinery of the War Office must not be hampered in the slightest degree, and it follows upon this that military medical service must be unconditional—or rather it had to be so in the comparatively early stages of what is going to be a long struggle. But we are now completing the third month of the war. The first terrific pressure on military and general organisation has been met, and met with considerable success. It was inevitable that there should be some places where order could not be so quickly established as in other places. It was inevitable, too, that shortage in one direction should wear an aggravated appearance owing to an absolute excess of provision in another. There are things which can be got quickly, and things which it takes time to procure. There are men exactly fitted for certain duties, who may not be immediately available; and men whose services can be obtained at once, while their services, however valuable, are unfortunately not exactly what is most urgently required at the moment. At the beginning of August the country was weltering in these troubles, the war having broken out with such suddenness, but in every direction confusion has steadily yielded to the tireless labour of organisation. And the time has certainly come now when small and particular adjustments could be effected, although these would have been impossible when crying needs made it imperative that all orders should be general and unconditional.

In particular it may, we think, now be possible to permit some medical practitioners, whom mobilisation has removed far from their ordinary sphere of work, and whose value to the community would be much greater in that sphere than elsewhere, to make exchanges; and we hope and believe that the War Office will permit of the flexibility thus suggested. In the first place, there is no shortage whatever of medical men willing to serve their country anywhere and in any capacity. To our certain knowledge several thousand practitioners are willing to place themselves at the disposal of the War Office, or have absolutely done so already. Some of these men are younger than others, and in many instances are discharging no duties which cannot be effectively discharged by others. They are surely indicated for service abroad rather than those men whose absence for an indefinite time in, say, India or Egypt would mean a dangerous loss to the community amongst which they carry on their medical practice. It must be understood that the question of shirking does not for one moment arise; we are not pleading the cause of any medical men who wish to be quit of their patriotic obligations.

We are perfectly convinced that every single medical man who has volunteered for service during the war, or who by the possession of a Territorial commission has become a part of our fighting forces, has only one idea, and that is to do his best for his country. But there are very many instances where a man will get into the wrong place unless some individual exceptions to general rules are permitted. It is very difficult for representation of this sort to be made by any medical man if the slightest suspicion should attach to him as one who has desired to avoid personal risks or expenses. But if it becomes clear that certain exchanges are sanctioned in deference to the public need, and in order to preserve the health of the community, while in no way endangering that of the troops, then no difficulty will arise. Undoubtedly there are some medical men at the present moment away from their practices, and under indefinite orders to remain away, whose regular work cannot well be done by proxy, while their medico-military duties would not suffer in other hands. Some of these medical men may be asked to serve under conditions of Imperial service, when a difficult case is much aggravated by its probable duration for a long time. We have here an example of what could not be avoided in the face of a sudden mobilisation—namely, profuseness and scarcity occurring simultaneously. Evidently there is now being provided an excess of scientific skill and attention in some directions creating a dearth of valuable services in other directions. But we are confident that the existing position is now appreciated by the War Office, and that no obstacles will be raised to certain methods of adjustment.

Annotations.

"Ne quid nimis."

NATURE AND NURTURE IN MENTAL DEVELOPMENT.

MUCH difference of opinion has always existed as to the relative importance of the factors of heredity and environment respectively in the development of the individual. At the one extreme is the attitude of Lombroso, who believed that criminals are born and not made; at the other is the view that the individual can be what he chooses to be. Social workers, ignorant of, or unfamiliar with, the facts of heredity as they impress themselves on members of the medical profession, are apt perhaps rather to concentrate attention on the matter of environment, and to emphasise the handicap imposed by uncongenial surroundings; still more, of course, by actual lack of the ordinary decencies of life, by overcrowding, insanitation, and the like. Medical men, again, who are brought into contact, it may be, with a hereditary *tare* showing itself in the third and fourth generation, and aware also of the extreme frequency with which a neuropathic heredity, similar or dissimilar, can be traced in the subjects of nervous and mental disease, as well as in the mere defective, *arriéré*, or *déséquilibré*, may feel that the individual can rise superior to his surroundings but not to his heredity, and consider that mental development to its full extent can never be expected in a child handicapped from birth. The problem is far indeed from being simple. Social, educative, hygienic elements—all that is indicated by the term "breeding"—contribute to the development of that healthy mind in a healthy body which is not always attained by mere biological excellence. There is, however, a deeper significance for the individual in the possession of a normally functioning body than that which the inheritance of an unblemished strain gives. There is more in mental health than integrity of the nervous constitution with which the individual is endowed at birth. Researches of recent years show that there is a biochemical association and interrelation of all the organs of the body, and that the ductless glands and sexual glands generate subtle and potent chemical substances whose action—nutritive, stimulating, and controlling—on the nervous system is of fundamental importance. Aware as we are of the rôle played by instincts and emotions in the building up of character, we may nevertheless be somewhat unprepared for the statement that natural physiological processes associated with the rise into activity of these glands are of integral importance in the development of the passions and sentiments. Viewed in this light, character is compact of traits whose underlying basis is dependent on the normal activity of hitherto little understood and appreciated glandular structures, which, as has been said, influence the nervous system to an extent scarcely realised. Those who are interested in this question—and who can afford to ignore it?—should read the recent Chadwick lectures delivered by Dr. F. W. Mott, and now issued in a small volume with the title that heads this annotation.[1] To any who have followed Dr. Mott's recent work they will not, perhaps, be found to contain any very new or novel observations; but the writer has put together, in a concise and practical form, many instructive data bearing on the problem, and his book will well repay perusal. He draws a distinction between the hereditary raw material of mentality and the social heritage slowly built up by man, of which, as he says, the brain is the receptor and storehouse, and shows that the finished product of education depends for its efficiency both upon a good mental and bodily raw material and opportunity of reaping the full advantages of the harvest of human thought and progress. Dr. Mott possesses the enviable faculty of making the meaning of his deep researches clear. Simple such problems as he deals with can never be, but here is an author who removes all needless obscurity.

THE CONTAMINATION OF ARMY UNIFORMS.

THIRTY-SIX years ago we published a report on the Contamination of Uniforms provided to the British Army made for us by Special Commissioners. At that time, and often with the laudable desire to help soldiers' widows, a good deal of work was given out from the Government army clothing depôts. This was notably the case at the Pimlico depôt, and our Commissioners traced the making of certain uniforms to houses where there were cases of scarlet fever and small-pox. The report naturally caused considerable sensation. Questioned in the House, Mr. Gathorne Hardy, Secretary for War, said there had only been one case of small-pox during the previous five years among those who at the Pimlico works had handled the clothes as they were brought back from private dwellings where they might have been in contact with cases of infectious disease. The pertinence of the reply was lost, however, when it was shown that there were only three persons so employed, and it was felt that the danger to the army of home tailoring in insanitary surroundings was very real. A much closer watch over the premises where uniforms were given out to be made was instituted at once, and later some measures of disinfection were introduced. It would seem that the danger is still with us, though the state of our public health is now so good that it may be present in a less degree, while legislation against sweating has been of good effect. However, no one can read the descriptions of the life in the trenches, especially such trenches as the Germans have built near Soissons, and which our troops may penetrate, without feeling the need of exercising the greatest care to prevent the advent of specific disease germs in the line of battle. Soldiers who have to lead a life of appalling hardship for weeks on end, in hourly touch with death, and literally soaked in their vile environment would form an easy prey. The evil is not yet eradicated. At Bethnal Green a few days ago a master tailor had to answer two summonses for neglecting to keep a list of the names and addresses of outworkers according to the law. The offence leading to the present prosecution was discovered by the sanitary inspector at Bethnal Green, who ascertained that a woman was at work making an army greatcoat in a house where scarlet fever had broken out. The master tailor had failed to keep a list of outworkers, though he had given out work to three persons. It was urged in court that there had been risk of carrying infection to the men who were laying down their lives for the country. Nevertheless, the defendant was only fined 10s. and £1 18s. costs. Now that so many uniforms are required and must be made at the utmost speed, the risk of such neglect as that just described increases in due proportion to the pressure brought to bear. Extra watchfulness is therefore imperatively necessary.

THE DANGER OF DIFFUSION OF TYPHOID FEVER AND CHOLERA BY OYSTERS AND ITS REMEDY.

Professor E. Bertarelli, of Parma, has drawn attention to the possibility of practical prophylaxis with regard to infection by oysters. Assuming as proved that the bacillus typhosus and the cholera vibrio are not found as habitual denizens in oysters, these molluscs must be held innocent in themselves, but if either of these germs, and more importantly the cholera vibrio on account of its greater motility, reaches the valves of an oyster through the medium of infected water it will be caught in the meshes of the parenchyma, and, so to speak, "squat" there. It is, moreover, an established fact that, given the infection of a tract of sea coast with the germs of typhoid or cholera, and seeing that sea water is a good life-preserver, the pathogenic germs in question are enabled to concentrate in the oysters with relative facility, maintaining themselves there for a considerable period without changing their characteristics. However, the sojourn of these germs in the oyster, provided the infection of the water is transitory, cannot last for long periods of time, and, as a rule, does not exceed one week, but may reach two. Acting on this fact, the writer suggests a method of abolishing the risk of infection. By placing an oyster which has been tainted into pure sea water it will gradually free itself of its accidental flora. This scheme has been put into practice in the reservoirs at Concarneau in France, sea water raised mechanically being first passed through coarse filters, then through sand. The sea water thus filtered passes into reservoirs containing the oysters, where the water is slowly changed. In from six to eight days the purification of the oysters is completed. The technical details of such an installation are not described, but are stated to be extremely simple. With regard to the cost, no precise figures can be given for keeping a definite number of oysters in reservoir, but if the data given by certain French undertakings are approximately true, it must be believed that the cost would be represented by a very few pence of increase in the price of a dozen of the molluscs, including in this increase the capital expenditure for the plant, mortgages, cost of pumping the sea water, and administration.

"TIPPERMALLUCH'S RECEIPTS."

Sir Walter Scott, in a memoir of his early life, penned about a century ago, records how at the age of three years he was often wrapped in a sheepskin taken from a newly slaughtered animal, and in this "Tartar-like habiliment" lay on the floor while his paternal grandfather and old General Sir George MacDougal, of Makerstoun, bent over him and tried to entice him to use his limbs by pulling their watches along the ground. He had fallen lame after teething, and his parents, though they were related to Dr. Wood and Dr. Rutherford, famous in the Edinburgh of their day, "grasped at every prospect of cure which was held out by the promise of empirics, or of ancient ladies or gentlemen." A raw skin or hide was, of course, supposed to be productive of strength. The idea lingers among savages to-day, but in the Scotland of 1774 it was pretty widely believed in by a nation famous for its education and rationality. That prince of sceptics, David Hume, died in 1776, but before his death the prevailing superstition in matters medical of his contemporaries had been strengthened by the publication of a second edition of "Tippermalluch's Receipts," a work which must be read to be conceived. Who "that worthy and ingenious gentleman" John Moncrieff of Tippermalluch may have been it is impossible at this distance of time to find out, for his name occurs in no biography and Tippermalluch figures in no gazetteer. There being a village of Malluch in Lanarkshire, however, we are perhaps right in inferring that Tippermalluch is in its neighbourhood, and that it belongs to the Celtic half of Scotland and had at one time strong Gaelic medical traditions. The book, which is comparable to the famous "Thousand Notable Things" of the south of England, of which an edition containing numberless quack remedies was published at Salisbury at the close of the eighteenth century, dates manifestly from a period long prior to 1775, when the second edition was published in Leith, or, indeed, from 1712 when the book first saw the light. So full of magic and of the influence of the stars are the "Receipts" that we are justified in supposing that they date from savage or pagan times. To quote only a few remedies. "The heart of a wolf eaten or drunken, cures the epilepsy." Again, "a wolf's skin worn about the middle" preserves from this disease. "For an hysterical passion, take the powder of the flesh of a wolf and wear a piece of the said flesh salted always about you." The last wolf is supposed to have been killed in Scotland in 1680, hence these remedies may be said to date from a period long prior to the eighteenth century. Others are concerned with amulets and charms. A ring set with a topaz is held to be a cure for "running of the reins." The root of satyrion held in the hand is an aphrodisiac. The hairs of a white dog hung round the neck are prone to mitigate epileptic fits, while coral and saffron, "rolled in the skin of a bladder" and hung round the throat cure a semi-tertian fever, as does an emerald worn in the same way. Plague may be cured by hanging the roots of the pimpernel round the neck, or by carrying about a carbuncle, ruby, garnet, hyacinth, sapphire, or agate. A man's own urine and fæces, passed through a cloth and drunk, are another remedy for the plague, while for fistula "a man's dung burnt, adding thereto powder of pepper, passeth all other kinds of cures." A "cancerous fistula" is cured by "ashes of a dog's head burnt." Goats' dung takes away pain and swelling. Dung is of constant use; this points back to the time when savages believed that excrement, urine, blood, and so forth, contained the immortal element in man. Akin to the foregoing usages is Tippermalluch's recipe for a wound in the breast—"Cause the patient suck the milk of a woman's breast, and also make injections of the same in the wound." Human milk is prescribed in the same way for consumption. The remedies are mostly older than the age of signaturism, and surprising as they appear there is a factor common to many of them—namely, the idea that the humours and excrements of the body are of medicinal value. As a rule, the old chap-books, printed in the South, are shy of appearing too openly superstitious, but in this work a long section is openly devoted to the subject of "mischievous acts, and putting of devils to the flight." St. John's wort, known as *fuga demonum*, hung in a house hinders these last. And we are further told that "whoever carries upon him eringo roots shall be preserved from witchcraft. The loadstone keeped upon a man removes disorder between man and wife. A pyot roasted speedily recovers the sick to health, and relieves all who have been enchanted from their birth." This prodigious book of pagan receipts was no sinister secret publication. It appears to have been sold by an enterprising bookseller, one William Coke, whose detailed list of wares must have rendered him extremely popular among all classes in Midlothian.

THE MEDICAL REGISTER.

WE wish to draw attention to the importance of notifying changes of address to the Registrar of the General Medical Council for insertion in the Medical Register. Omission to do this sometimes leads to a temporary removal of the name, with its consequent inconvenience; and apart from this the Register is the official list of the medical profession, and all should assist to keep it accurate. The Register is now singularly free from error, but it can only be kept so by the coöperation of the medical profession, who are urged to send all alterations of residence at once in a legible hand to the Registrar at 299, Oxford-street, London, W., and such communications should be signed with the full name. A statement of the difficulties which arise through failure on the part of practitioners to advise the Registrar of their changes of address will be found in a letter from Mr. A. J. Cockington, the acting Registrar, which we publish this week. Proceedings in the courts have shown that the slackness of certain members of the medical profession in this respect has been taken advantage of by the impersonating rogue.

PLAGUE CLOUDS IN SOUTHERN EUROPE.

Apart from imported cases and a few localised outbreaks, of which the Oporto epidemic in 1899 was the most serious, Europe has enjoyed a comparative immunity from plague during the 20 years in which the present pandemic has been ravaging most quarters of the globe. During the past few months, however, outbreaks of the disease have been reported in three countries in Southern Europe—namely, Greece, Italy, and Portugal—in the order named, as well as in certain Levantine ports which are in frequent communication with Europe by means of shipping. It is well known to epidemiologists that since 1899 plague has been annually epidemic in Egypt, including the Mediterranean ports of Alexandria and Port Said, and that the malady has manifested itself at various ports on the coast of Syria and along the southern and western shores of Asia Minor. During the summer months of the current year plague was reported to have occurred in the ports of Jaffa, Beirut, and Tripoli in Syria, and in Adalia and Smyrna in Asia Minor.[1] The disease also appeared shortly afterwards in several islands in the Ægean Sea lying off the western coast of Asia Minor, including Rhodes, Chios or Scio, and Mitylene or Lesbos; its presence was likewise observed about the same time in the Greek island of Syra, the most important of the Cyclades. In September several cases of plague were notified at the port of Salonica on the coast of Macedonia, and at Piræus, the port of Athens, 12 persons were attacked by the disease. During the same month a group of ten plague cases occurred in the seaport town of Catania in Sicily, and early in October eight other cases were reported in Portugal, in one of the suburbs of Lisbon. It is probable that the islands in the Ægean Sea were infected from one or other of the affected ports in Asia Minor, and that the infection was carried from these islands westwards to Greece and perhaps to Sicily, though locally Alexandria is regarded as the source of the mischief in the latter case. In this connexion it has to be remembered that the islands of Chios and Mitylene have been held by Greece since the last Balkan war, and that Rhodes is at present occupied by the Italians, so that it is not unlikely that the disease may have been conveyed through shipping from the occupied islands to Salonica, Syra, and Piræus on the one hand and to Catania on the other. The recent infection of the Lisbon suburb is more difficult to account for, and as yet no definite information is available to explain the occurrence. So far as is known Portugal has remained free from plague since the early months of 1900, when the Oporto epidemic of 1899 came to an end, after 310 persons had been attacked, of whom 107 died. The origin of that outbreak appears never to have been satisfactorily cleared up. As regards current plague in Portugal's possessions outside Europe the presence of the disease in the island of Terceira, in the Azores, was reported last December, but no cases have been heard of during the present year. It is, however, possible that the disease has been appearing in the Azores during 1914, and that cases have been intentionally concealed, or have been overlooked owing to their mild character. The infection, therefore, may have been brought by ship from Terceira to Lisbon. Be this as it may, the fact remains that groups of plague cases quite recently have occurred almost simultaneously in Greece, Italy, and Portugal. These outbreaks will doubtless be dealt with in a satisfactory manner by modern methods with a view to prevent any further extension of the infection, and British port medical officers of health will also no doubt be keeping a sharp look-out for vessels hailing from the infected ports of Southern Europe and the Levant so as to avert the landing of plague upon our own shores.

At the conclusion of the delivery of the Harveian oration by Sir Richard Douglas Powell before the Royal College of Physicians of London on Monday last, Sir Ronald Ross, F.R.S., was presented with the Bisset Hawkins Memorial medal for distinguished services in the advancement of sanitary science and public health.

The Bradshaw lecture on "Some Clinical Contributions to the Study of Glycosuria" will be delivered before the Royal College of Physicians of London by Dr. Nestor Tirard on Tuesday, Nov. 3rd, at 5 o'clock.

FURTHER NOTES UPON THE WOUNDED IN THE PRESENT CAMPAIGN.[1]

By G. H. Makins, C.B., F.R.C.S. Eng.,
COLONEL, A.M.S.; CONSULTING SURGEON TO THE FORCES OVERSEAS.

Oct. 14th, 1914.

The last fortnight has seen a great decrease in the number of wounded men in the hospitals both in Paris and along the western lines of communication, while it is now possible to form a more definite opinion as to the progress made by the wounds themselves. Subsequent events have by no means belied the impression gained at an earlier date, that the wounds would do well when the patients could be at rest and under more satisfactory conditions. The means of transport have been very materially improved both with regard to the hospital trains themselves and as to the rapidity with which the patients can be removed to the general or stationary hospitals. Under certain conditions the increased fleet of motor ambulances has also proved of value, but the cars are only suitable for cases that can bear much shaking.

I have just returned from a visit to the hospitals along the western lines of communication and have had the opportunity of seeing a number of the more severe cases after an interval of 14 days. A very great difference is to be observed; although the wounds have been suppurating the patients are in good condition generally, and locally granulation has been rapid and healthy with steady contraction of the deep cavities and extensive wound surfaces. The gangrenous cellulitis has disappeared, and it appears probable that the most serious factor in the infections was streptococcic in nature. It is to be hoped that with the more settled military conditions now existing this complication may become a thing of the past. Multiple proximal incisions proved the best method of treatment.

---

[1] The Lancet, Oct. 10th, 1914, p. 905.

The Treatment of Tetanus.

In this region the more serious complication of tetanus has also become far less common in concurrence with the less seriously septic state of the wounds. It is still too early to form any opinion as to the success of the prophylactic measures which have been resorted to, but much is to be hoped for from them, and possibly a still greater advantage may be gained from the removal of our troops from a district in which tetanus is notoriously common amongst the civil population in times of peace.

The methods of treatment which have been adopted have ranged over the whole area of past experience, the only routine plan having been the injection of antitetanic serum in large doses. At the Pasteur Institute, where two cures have been obtained, serum treatment by subcutaneous injection was the main element; at other hospitals the serum has sometimes been administered intravenously or by the intrathecal route. Beyond this, in some cases 20 per cent. peroxide of hydrogen solution has been injected subcutaneously and oxygen inhalations have been tried, while in all peroxide of hydrogen has been employed locally to the wound. Subcutaneous injections of magnesium sulphate have been tried to control spasm. Especially at Angers subcutaneous injections of 2 per cent. carbolic acid have been the favourite treatment, as much as 22 grains being administered per diem without any unpleasant results. Both in the English and French hospitals there this method was regarded with much confidence, and at No. 5 General Hospital I was shown two cases upon the high road to recovery treated by this method in combination with serum. In a large majority of all the cases chloral has been given by mouth or by rectum in large doses, and chloroform inhalations have been resorted to for severe and painful spasm.

In spite of this very varied treatment the main factor in the prognosis has, as in past experience, proved to lie in the length of the incubation period. Few if any cases have recovered where symptoms developed before the tenth day following the wound. Of some ten cases promising recovery which have come under my own observation the incubation period varied from 10 to 15 days. The type of disease has been somewhat variable, the only constant features being the "facies" and trismus. In the most acute cases general spasm was not infrequently absent, but in these the intense general septicæmia no doubt overshadowed the purely tetanic signs. In many cases local spasm of the affected limb, often extremely painful, has been a marked character.

Local surgical measures have been little employed; the wounds have been too large for excision, and in the few instances in which amputation of a limb has been resorted to no favourable result has been attained. The same may be said about the method favoured by some of the French surgeons of dividing the great sciatic nerve when the leg or foot was the seat of injury.

Nature of Injuries.

With regard to any special characteristics of the local injuries not much remains to be said. The common lodgment of fragments of shells is naturally a marked feature, also the very large area of laceration within when the wound of entry is comparatively small, suggesting a revolution of the missile within the limb continued after the moment of impact. I have twice seen the iron wad of a shrapnel shell which had been removed, once from the leg, and once from the buttock, in either case the missile having entered edgeways by a very moderate-sized slit wound. Retained pointed bullets are far from uncommon, and, as has been before remarked, contour wounds, especially around the chest wall, are often seen. Wounds of the head seen in the hospitals are of the tangential type in a very great preponderance; those traversing the skull are comparatively rare. This is no doubt to be explained by the frequency with which the injuries are caused by shrapnel bullets travelling with low velocity. The depressed fragments produced by the shrapnel bullets are of a larger size than those resulting from blows from rifle bullets of small calibre. There seems little doubt that the injuries produced by the English bullet are more severe as a rule than those resulting from the German. It may be that this is partly due to a lower velocity of flight in the case of bullets fired from machine guns, which are so freely used by the German army. Either bullet, however, when striking with high velocity is prone to fragmentation. Trephining of the skull performed for local pressure symptoms has as a rule been followed by very gratifying results, more or less complete recovery from paralysis occurring in many cases, showing that the area of destruction is not necessarily great. The spinal injuries are as usual of a depressing character, but where paraplegia has resulted from shrapnel wounds not actually impinging on the spinal canal recovery seems more rapid than in the case of similar signs accompanying wounds by bullets of small calibre. Signs of union are evident in a considerable proportion of the compound fractures.

Installation of a "General Hospital."

A number of the general hospitals are now in full working order, some installed in buildings, some utilising their tents. The Indian type of marquee is admirable for hospital purposes. The very full and complete equipment of these hospitals is very readily adapted for use within a building, in which case the tents can be stored or are available if extension of accommodation is needed. A number of the hospitals have been accommodated in buildings, some in large hotels or club premises, others in school buildings. No. 4 General Hospital at Versailles is established in the luxurious Trianon Palace Hotel; the general excellence of this hospital has already been adverted to in the public press, and it has been doing a large amount of good work. Such buildings, as is the case with smaller similar hospitals in Paris, possess the advantage of some very excellent large wards in the public rooms and abundant bath and sanitary arrangements, but are somewhat more difficult to work on the upper floors from the number of rooms in which the patients are distributed. This difficulty is reduced to a minimum in the Trianon Palace Hotel in consequence of the simplicity of the building, all the rooms being arranged on either side of long straight corridors running the whole length of the hotel. Up to the present time the patients have also enjoyed the great advantage of a charming garden in which those who are up can roam or sit the greater part of the day.

A somewhat more difficult problem is presented when a building not designed for residential purposes is provided. A good illustration is afforded by No. 5 General Hospital, which had allotted to it a large new school building, nearing completion, but not yet equipped for its purpose. The building had been first utilised as a temporary barracks, and when the soldiers went out it was left in the condition not uncommon after temporary occupation by troops. The first task was to cleanse the building itself and clean up the surrounding ground which had served the purpose of a general latrine. The water-supply of the town was connected with the pipes already existing within the building, and electric light was installed throughout. The type equipment of a general hospital was then introduced to convert the empty rooms to their new purpose, and in a few days several hundred patients were admitted for treatment.

A commodious operating theatre, well lighted for use by day or night and thoroughly equipped with instruments and sterilising apparatus, was arranged, and in an adjoining room the X ray outfit was set up. On an upper floor a pathological laboratory was established. To supplement the sanitary arrangements of the building a range of latrines was set up in a distant part of the grounds for the use of patients not confined to bed and the staff of orderlies. The latter were lodged in tents erected in the grounds. Beyond this an excellent dispensary and the store-rooms necessary for the working of a general hospital were established, and also a service lift for the conveyance of stores to all four floors, the latter at the extraordinarily modest cost of 310 francs.

A thoroughly efficient hospital was thus obtained in the course of a few days. At the time of my visit a large amount of work had been done there, and to illustrate the thoroughness with which it was performed I may mention that the skiagram of every fracture or case in which a missile was retained was to be found by the side of each patient's bed, and of many of these excellent prints had been made; there were also photographs of several of the recent wounds. In the laboratory I saw cultivations from some of the wounds, and the organism in the blood of a case of enteric then present in the hospital. Much ingenuity had been shown in the devising of splints, especially in the employment of the aluminium bands forming a part of the service equipment.

The cases throughout were doing well, and judging by my own experience no better military hospital on active service could be wished for. I have purposely chosen this hospital for description because it appears to illustrate the initiative required in the installation of a "general hospital" under unusual conditions which have no doubt had to be met with elsewhere, and which are not, I think, fully appreciated by those without experience of active service.

PLYMOUTH INSURANCE COMMITTEE.—Owing to want of funds the Plymouth Insurance Committee has been unable to settle in full the accounts of the local chemists who are dispensing under the National Insurance Act. This has given rise to a considerable amount of dissatisfaction, and last week a deputation waited upon the Members of Parliament for the borough and urged them to use their influence with the Government to get more money provided for the purpose.

EPSOM AND EWELL WAR HOSPITAL.

By EDMUND OWEN, F.R.C.S. ENG.,
SURGEON TO THE FRENCH HOSPITAL, LONDON.

AT the outbreak of the war thoughtful people at Epsom and Ewell decided to equip a hospital for the reception of wounded soldiers, and they were fortunate enough to acquire for this purpose, through the kindness of the Grand Stand Association, the large new building for the restaurant at the Grand Stand, and they at once set to work to prepare it for the object in view. Shortly after this the medical staff asked me to act as consulting and operating surgeon as circumstances might require. I was given to understand that the patients sent there for treatment would probably be such as would merely need rest after having been dealt with at some other institution, Epsom being rightly regarded as an ideal place for convalescents. The building, having been duly furnished and equipped, was visited by an official from the Royal Army Medical Corps, who was so pleased with the place that he informed the local medical staff that they might, after all, be called upon to receive more important cases than they had been led to expect.

On Thursday, Oct. 15th, the local staff were told that the reception of 31 cases was to be provided for in the course of an hour or so, that the men had just been landed at Dover, and that they were coming *viâ* Guildford. Mr. Nigel Colman and others had motor ambulances waiting at the South-Western Railway station, and many other friends helped with cars and taxis, the station and its approaches being kept clear by drafts from the Universities and Public Schools battalion which is in training at Epsom. The station-master had thoughtfully arranged that the train coming up from Guildford should be emptied of its patients upon the *down* line, so that the wounded could be placed in the ambulances on the side convenient for the Grand Stand, as otherwise they would have to be taken across the line by an awkward subterranean passage or in some other way. Nothing could have been better. But unfortunately some less sympathetic but more highly placed official descended from Waterloo Station and upset the plan, insisting that the stretchers should be carried down the steps, along the subterranean passage and up the stairs on the other side, and he absolutely refused to allow the adoption of the proposed arrangement for the comfort of the soldiers. His interference in the matter caused great discomfort and unhappiness. This, however, seemed to be the only hitch in the evening's work, which had all been very carefully planned out.

At about 8 o'clock P.M. I received an urgent call to Epsom, and was asked to bring instruments with me, as it appeared that some of the men who were even then arriving were evidently in a very bad way.

Notes of Cases.

The first case brought into the improvised theatre was a man with an opening into his abdomen from which a piece of omentum of the size of a small glove was hanging. The wound was foul and suppurating. The parts were cleaned up with tincture of iodine. The omentum was drawn out a little further, tied in two pieces, and cut off, the wound being covered with an iodine pad. No sutures were used.

The next man placed upon the table had a bullet-wound of entrance in the buttock of the size of a small pea, whilst the tissues at the front of the groin, at the exit wound, were very widely blown away, the sartorius and much of the vastus externus being torn across and the skin being widely destroyed. The damage done at the field of exit of the bullet was remarkable and suggestive. The wound was septic.

The third case was one of compound, comminuted fracture of the humerus just below the shoulder-joint. This was one of the worst cases which we had. However, we did our best to try to save the limb, removing many loose fragments of bone and carefully swabbing out every part of the large septic wound with tincture of iodine. It was felt at the time that the probability of amputation being demanded was great, but it was deemed right to give the man the chance. The next day he was comfortable, but on Saturday afternoon, when the wound was dressed under an anæsthetic and again explored, it was unanimously agreed that amputation should be done through the shoulder-joint on the following day—provided the man gave his consent. Amputation through the shoulder-joint was performed on Sunday afternoon last.

Another man had a wound a little above the great trochanter of the left femur; the bullet had comminuted the upper end of the thigh bone and had made its escape through the back of the perineum, where was a lacerated wound discharging pus. The case was one of extreme gravity, but it did not lend itself to active surgical measures. It was impossible even to render the wound aseptic. On Sunday afternoon the man expressed himself as feeling much better. We found him smoking a pipe and reading a magazine, and he is now doing well on a Hodgen's splint.

Amongst other serious cases of bullet wounds was one of compound, comminuted fracture of the external malleolus. On account of cellulitis and extensive suppuration amputation below the knee was performed last Wednesday morning. In a case of injury to the knee it was impossible to be sure whether the accompanying synovitis were septic or not. This man was brought into the theatre on Monday afternoon, an X ray picture having been taken of the knee on the previous evening by Mr. Ede with an apparatus which he had set up in the building. The plate showed with great clearness a bullet on the outer side of the femur, but so far above the ordinary position of the synovial membrane that we all agreed that it must surely be outside the joint. On cutting down to the bullet through the vastus externus and feeling for it with the finger it at once slipped away, and had evidently hidden itself in the joint. On freely opening the synovial membrane and passing the finger under the patella it was found near the inner tuberosity of the tibia, from which place it was no easy matter to fish it out across the joint. The joint contained much fluid and some jelly-like material and a mass of decolourised blood clot. Two pieces of loose cartilage were also found and removed. As it was probable that the interior of the joint was septic it was washed out with some hot chlorinated soda solution and a drainage-tube was inserted.

Among other cases I may mention also one in which the chest was implicated and the adjacent area of the lung was dull and crepitating; one in which the abdomen was involved, and one in which the soft tissues of the loin had been widely undermined. A most unfortunate feature was that every wound was septic. On Sunday afternoon the men were all going on well.

One young soldier was so ill at the railway station that he was expected fatally to collapse before reaching the hospital, and when he was placed in bed he was almost pulseless. He was treated by infusion and by the injection of adrenalin. He had a bullet wound above each great trochanter, and as there was some blood in his urine we feared that his bladder might be damaged. He was so ill, however, that exploration was out of the question; but as he was slightly better in the morning we thought it right to take the risk of placing him under an anæsthetic. On passing a catheter we drew some blood-stained urine, but the bladder held apparently all the sterilised water which we injected. Placing him in the Trendelenburg position we rapidly exposed the front of the bladder without opening the peritoneum, and it was then found that the bullet had traversed the roof of the urethra, and that a leakage of urine was taking place from an opening just behind the triangular ligament. We therefore closed the surface wound, leaving a space above the pubes for drainage. But notwithstanding the adoption of further active measures against collapse the unfortunate lad sank exhausted.

Amongst the 31 cases there were many others of a serious nature which were dealt with by Mr. Andrew McAllister and by the members of the hospital staff, Dr. T. A. Alexander, Mr. T. L. Braidwood, Dr. E. G. C. Daniel, Dr. John Ferguson, Dr. C. A. Ormerod, Dr. W. H. Rayner, Dr. E. N. Reichardt, and Dr. W. Thornely, and myself. We were all kept busy from late in the evening until nearly 4 o'clock in the morning.

What specially struck me was the sublime courage and endurance of these wounded men. There was never a word of complaint or impatience. But soldiers are much alike, I suppose, all the world over. We have, for instance, about 30 wounded Belgians under treatment at the French Hospital in London who are just as uncomplaining and cheerful, and I doubt not that the German soldiers are equally good patients. It is a great thing to be a soldier: he is usually a real *man!*

The Hospital and Staff.

In conclusion, I would like to speak critically of this hospital, which has been established at the Grand Stand. I have never been in wards which are more attractive or satisfactory. The bedding, furniture, and linen are most excellent, and it was pleasant and reassuring to see these wearied soldiers decked out in the flannel garments which most of us know so well by sight, as we have watched them being cut out and made up by our womenfolk at home. I can assure our needle-workers that their labour is of the utmost value. Many of the men fell sound asleep the moment they were put into bed, and one was loth to wake them as their turn came for examination; but it had to be done. One of them said to me, "What a treat to be brought to such a place as this." He was grateful for the thoughtful kindness shown him; soldiers always are delightful people to have as patients.

The hospital is staffed by a resident medical officer, Mr. W. B. Peacock—a gentleman who struck me as being remarkably well suited for the post—a matron and a staff of eight nurses, some willing ambulance ladies, and a squad of four men of the

St. John Ambulance Brigade. These men did the shifting of the patients to and from the operating theatre and helped in the orderly work of the place. They belonged to the Maidenhead division, and if their instructor, Dr. R. E. Whitting, could have seen them carrying on he would have felt himself well repaid for the great pains and care which he has evidently devoted to their instruction. Nothing has shown the value of the work of the Order of St. John in time of peace more clearly than the way in which the services of the members of the brigade have been drawn on since the outbreak of the war; between 5000 and 6000 of them are now engaged in the field or in hospital work as orderlies. Not only is this a valuable help to the medical department of the army, but it is also a clear proof to men and women who have been giving so much of their leisure and thought to the advancement of the Brigade (on what some people may have regarded as sentimental grounds) that the work of the Order has been based upon a foundation which is as solid and useful as it is ancient.

THE CLAIMS OF BRITISH SPAS.

(Continued from p. 958.)

IV.—Droitwich.

The reputation of Droitwich as a health station is based almost entirely upon its famous brine wells. The confidence in the curative properties of these potent saline waters is such that auxiliary aids to treatment are seldom employed, although they are available. The waters are saturated with salt, and they could not hold a grain more than they do, since the limit of solubility is reached by contact with the rock-salt deposits below. The slightest evaporation of the water leads to the deposit of salt. The specific gravity of the brine is 1·195 and the total salts amount to no less than 317·328 grammes per litre, or about 26 per cent. Amongst salts present are the sulphates of sodium, calcium, and aluminium and chloride of sodium, but these altogether amount to about 7 grammes per litre. The brine is decidedly radio-active. It is important to observe that the salt obtained on evaporation obviously loses its radio-activity in the course of this process, and that therefore the brine of Droitwich cannot be imitated by dissolving any salt obtained by evaporation in water again.

Treatment at Droitwich succeeds mainly by its favourable influence on nutrition, whilst, when necessary, the diet of the patient is carefully regulated. The medical authorities at Droitwich make few and simple claims for the therapeutic uses of the water. They do not set out a wide category of disorders as all receiving relief from brine treatment. But while this is the case, the value of these waters in the treatment of gout, rheumatism, sciatica, the uric acid diathesis, and in completing the recovery process of acute illnesses has been well established.

There are two bathing establishments at Droitwich—the St. Andrew's and the Royal Baths. In 1836 the latter were opened, and since that time a very large number of patients suffering from rheumatism, sciatica, gout, and nervous disorders (insomnia) have sought relief at Droitwich. The baths have now grown to the dimensions of a continental spa; hotel accommodation has been increased and improved, and every effort is put forward to make the place attractive to the visitors. Important extensions were made to the St. Andrew's Brine Baths in 1907. These additions consist of an enlarged entrance hall, lounge, waiting-rooms, and a new series of ladies' baths, all well planned, substantially built, and conducive to the comfort of the patient. There are also two large swimming-baths, one for ladies and the other for gentlemen.

Graduated exercises can be performed with advantage in this natural brine. The buoyancy of the water is so great that the bather can lie on the top as though lying on an air bed. He cannot possibly sink. When lying upon the water the limbs are equally supported in every direction, and the patient can thus perform certain movements which he could not attempt on *terra firma* on account of the pain. These exercises are claimed to have been successfully employed in the treatment of scoliosis and to exercise painful joints, and are thus most useful during the convalescent stage of sciatica and in the after-treatment of fractures and other surgical injuries.

Altogether the accommodation provided includes private hot reclining baths, douche, needle, vapour, deep chair baths, and three commodious and elegant brine swimming baths. There are also special rooms for Aix douche baths, and effervescing baths on the well-known lines of treatment for chronic diseases of the heart at Nauheim.

Social attractions are well looked after; there is a golf course, and the neighbourhood abounds in places of beauty and interest, as, for example, Worcester, Malvern, Tewkesbury, Gloucester, Hereford, Stratford-on-Avon, and Kenilworth.

The Droitwich waters occupy amongst balneological stations a unique place, since no other water is known to possess the same saline strength. It is physically and chemically impossible, in fact, for a water to contain more salt than Droitwich brine, since it is saturated under some pressure in the natural wells beneath. It is about ten times the saline strength of sea water.

(To be continued.)

Royal Academy of Medicine in Ireland.—The following have been elected office-bearers for the ensuing year:—President: Professor Walter G. Smith, M.D. General Secretary: Professor J. Alfred Scott, M.D. Foreign Secretary: Sir John W. Moore, M.D. The sectional presidents will be as follows:—Medicine: Professor J. A. Lindsay, M.D.; Surgery: Professor F. Conway Dwyer, M.D.; Obstetrics: Dr. M. J. Gibson; State Medicine: Dr. T. P. C. Kirkpatrick; Pathology: Dr. J. B. Coleman, C.M.G.; Anatomy and Physiology: Professor E. J. Evatt, M.D.

Lectures on Infant Care.—To meet the demand for training expressed by many voluntary health workers enrolled since the war for service at local infant welfare centres, &c., the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy, in coöperation with the Association of Infant Consultations and Schools for Mothers and the Women's Imperial Health Association, is holding a course of lectures on infant care in London at the Royal Society of Medicine, 1, Wimpole-street, W., on Mondays, and at the Medical School of Charing Cross Hospital, 62, Chandos-street, W.C., on Thursdays, from Oct. 19th to Dec. 17th, at 5.30 P.M. In addition to the lectures facilities will be provided for gaining practical instruction through attendance at infant consultations, and classes will be held at certain selected centres. An examination will be held at the close of the course and certificates awarded. The fee for each student is 5*s*. Further particulars may be obtained from Miss Halford, secretary, National Association for the Prevention of Infant Mortality, 4, Tavistock-square, London, W.C.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

WE publish this week a first series of results obtained at various stations in the country in regard to the quantity and quality of the deposit collected out of the atmosphere by the standard gauges set up at these places. The tables below give the rainfall for the months ending April 30th and May 31st, 1914, and the amounts found of insoluble matter (tar, soot, dust) and soluble matter (sulphates, ammonia, and chlorine) in the volume collected. It will be seen that the laboratory findings are calculated into metric tons of deposit per square kilometre during the month. One metric ton per square kilometre is equivalent to approximately 9 lb. per acre, or 2·56 English tons per square mile. These comparative figures are well worth studying, inasmuch as they show considerable variations in the degree of atmospheric pollution at different stations. To take one example, Malvern shows for the month of April a total deposit of solid matters of 1·76. These contained no tar at all, and but little carbonaceous matter. In the same period, however, at Liverpool the total solids amounted to 15·97 metric tons, and the tar to 0·36 ton. All through there are most interesting and significant comparisons to be made, and when the series for the year is completed a very valuable and instructive record will be available. The Committee for the Investigation of Atmospheric Pollution may be heartily congratulated on the practical movement they have successfully organised to obtain actual records of the atmospheric pollution which is taking place throughout the country.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION:

Summary of Reports for Month ending April 30th, 1914.

1	2	3	4	5	6	7	8	9	10	11	12
Place.	Correspondent.	Rainfall in millimetres.	Metric tons of deposit per square kilometre during month.								
			Insoluble matter.			Soluble matter.		Total solids.	Included in soluble matter.		
			Tar.	Carbonaceous other than tar.	Ash.	Loss on ignition.	Ash.		Sulphate as (SO_4).	Chlorine (Cl).	Ammonia (NH_3).

Col. 4 includes all matter insoluble in water but soluble in CS_2. Col. 5 includes all combustible matter insoluble in water and in CS_2. Col. 6 includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (*a*) Approx. 9lb. per acre; (*b*) 2·56 English tons per sq. mile; (*c*) one gramme per sq. metre; (*d*) 1/1000 millimetre of rainfall (see Col. 3).

Similar results obtained in THE LANCET Laboratory in regard to the pollution of the metropolitan atmosphere have already been published in our columns,[1] and the future records of the committee as they come forward from month to month will be issued. We are undertaking ourselves in THE LANCET Laboratory the analysis of the deposit collected at the Meteorological Office in London.

THE SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH.

IT may seem to some an ill-chosen opportunity to forward the claims of the South African Institute for pecuniary support, but in our opinion no better time could have been selected than that in which, on the one hand, the powerful and loyal support of South Africa is being given us in our struggle against Germany, and on the other the need for organised medical research is being brought home to us by military conditions. The South African Institute for Medical Research was established in Johannesburg under the joint control of the Government of the Union of South Africa and the Transvaal Chamber of Mines. The Government contributed the site and has made itself responsible for an annual subsidy of £5000, while the mining industry has provided the building and equipment at a cost of £40,000. Hitherto the energies of the Government have been directed towards veterinary research, upon the results of which the progress of South African agriculture largely depends. This useful branch of work has been most liberally supported by the Government, and has been carried on under Sir Arnald Theiler, the Director of Veterinary Research in the Transvaal and the author of many publications on the tropical diseases of domestic stock which have attracted much attention. The support which the Government is extending to medical research is further evidence of the enlightened and progressive spirit now animating the great self-governing subcontinent.

The buildings of the institute which crown the hill to the north of Johannesburg were designed by Mr. Herbert Baker and Mr. G. G. Fleming, the former of whom is one of the architects commissioned to design the new capital of India at Delhi. Sir Almroth Wright when on a visit to Johannesburg gave advice as to the general plan. The further elaboration of the details was entrusted to Dr. W. Watkins-Pitchford, then Government Bacteriologist for the Transvaal. Dr. Watkins-Pitchford, who has now been in Johannesburg for some three or four years, is the director of the institute; he was for ten years Government Pathologist to the Natal Government.

The institute has already published four memoirs, the first of which constitutes a very able study, from the statistical side, of Pneumonia as it affects the Native Mine-labourer. This memoir was reviewed at length in our columns on its appearance. The second and third deal with the Serological Classification of Pneumococci and the Ash of the Silicotic Lung respectively. A fourth publication, which has not yet reached us, is announced, and, like the first, is by Mr. G. D. Maynard, who was secretary of the Government Commission on Miner's Phthisis.

The institute is, unfortunately, not endowed in any way and depends for the carrying on of its work upon the generosity of private individuals, and we can recommend its claims to those of our readers who may be able to bring them to the notice of members of the public. The institute already makes a special appeal to those whose wealth has been drawn directly or indirectly from the gold or diamond mines of South Africa, but having regard to the basis of its establishment it may fairly be said to deserve the support of all. There is no intention of confining its work to industrial or topical diseases; all matters concerning the health of the inhabitants of South Africa will come within its scope. It is hoped, moreover, that, with the general advancement of scientific and technical education in South Africa, facilities may be afforded for teaching modern developments of pathology and bacteriology in association with the work of research. Research will be kept in the foreground as the proper work of the institute, but that the teaching side has not been forgotten is indicated by the provision of a lecture theatre, which is also to be available for meetings of the local medical profession. It is hoped consequently that men of

South African Institute for Medical Research.

wealth and liberal minds will endow research fellowships in particular subjects so as to insure a continuous contribution to the study of human disease.

The enterprise is being administered by a joint committee consisting of Government nominees and leading representatives of the mining industry, under the chairmanship of Mr. P. Ross Frames, the managing director of the Premier Diamond Mining Company.

The institute's buildings embody the latest ideas in medical research, and include five wards for the reception of patients. In these wards, which will be nursed from the adjoining Johannesburg General Hospital, the phenomena of disease will be recorded under laboratory conditions and the best methods of treatment ascertained by close observation and comparison.

The Government and the mining administration of South Africa are to be congratulated upon their enlightened enterprise, an enterprise which should not be permitted to languish for want of financial support. The prosecution of medical research is one of the high functions of man, a manifestation of that spirit of humanism which will bear sway when barbaric militarism has disappeared from among the civilised peoples: the moment when South Africa is proving in a very patriotic and practical way her willingness to bear her part in an imperial war on behalf of peace would be a very fitting one to place the South African Institute for Medical Research on a firm financial footing.

PRISONS COMMISSIONERS' REPORT.

THE report of the Commissioners of Prisons and the Directors of Convict Prisons for the year ended March 31st, 1914, has been presented to both Houses of Parliament by command of His Majesty. It is signed by Sir Evelyn Ruggles-Brise, K.C.B. (chairman), Mr. F. J. Dryhurst, C.B., Captain C. F. de L. Eardley-Wilmot, Mr. M. L. Waller, and Sir Herbert Smalley, M.D.

Statistics as to Local and Convict Prisons.

The report states that the daily average population in local prisons was 14.352, in convict prisons 2704, in Borstal institutions 928, in State inebriate reformatories 81, and in private detention prisons 171. As compared with the previous year these figures show a decrease of 1182 in local prisons and 172 in convict prisons. The receptions into prisons during the year numbered 128,686 on summary conviction and 7738 on conviction on indictment—total 136,424. The death-rate in local prisons from natural causes was 0·55 per 1000 prisoners received, the average for the previous 25 years being 0·50 per 1000. The death-rate from natural causes in convict prisons was 7·4 per 1000 of the daily average population, as compared with 3·9 in the preceding year and 6·3 for the past ten years. The number of persons in local prisons found to be insane and certified as such after reception was 140, as compared with 135 last year; and in convict prisons 44, as compared with 48. Of the 140 cases certified in local prisons 100 were found to be insane on reception, and 8 exhibited symptoms of insanity within a month of reception. Many of those who were in prison for some time before the usual symptoms of insanity were observed were known to be of weak intellect or mentally impaired on reception, or to have been previously insane. The number of prisoners who were released from local prisons on medical grounds (exclusive of pregnancy, &c.) was 38, and from convict prisons 2. There were 11 suicides in local prisons during the year and 1 in convict prisons. The number of prisoners formally recognised as being so feeble-minded as to be unfit for the ordinary penal discipline was 843 in local prisons and in convict prisons 108. It is hoped that the passing of the Mental Deficiency Act, which came into operation on April 1st, 1914, will, as soon as the necessary operations can be made by the newly created Board of Control, relieve the prison authority of a great burden and responsibility in dealing with these cases. It is estimated that about 70 per cent. of such cases will satisfy the definition of the Act and will henceforth pass under the control of the body specially appointed to assign the proper treatment necessary in each individual case.

The majority of our prisons are now (the report proceeds) equipped with special cells for prisoners suffering from tuberculous disease. It is satisfactory to note that at Birmingham Prison, where 26 (25 male and 1 female) prisoners were found to be suffering from phthisis on reception, all showed some improvement during their imprisonment in the suitable environment provided, and medical officers generally report favourably on the facilities now given for the special treatment of tuberculous disease.

Habitual Inebriates—Anthropological Investigation.

With regard to the habitual inebriate under State control, of both sexes, it appears from the report of the inspector, Dr. R. W. Branthwaite, that the population at both institutions—Warwick and Aylesbury—for males and females respectively is rapidly decreasing, the daily number under detention at the former being only 19 and that at the latter only 62. Dr. Branthwaite says that "unless some effort is made to secure the passage into law of a consolidating and amending Bill this excellent attempt to institute more rational methods for dealing with habitual inebriates, at any rate with those who haunt our courts and prisons, is doomed to failure." If, as stated in the report, there are sufficient indications to justify the belief that a measure of mental defect exists, in many cases, from birth or early age, it may reasonably be anticipated that in course of time, when the Mental Deficiency Act is in full operation, such cases will have been eliminated, having been certified as mental defects.

Referring to the publication in August last of Dr. C. Goring's report, recording the results of his anthropological investigation in convict prisons, the Commissioners remark that whatever reception is given to the various conclusions arrived at there can be no doubt that the anthropological data, presented in a series of tables, are of great scientific value. "This praiseworthy work is an attempt to present an outline of conclusions reached by the application of the statistical method to the data furnished by inquiry as to the physical and mental condition of convicts in English prisons. Close mathematical analysis of these data, within the admitted limits of the inquiry pursued with remarkable patience and ability, points to the conclusion that there is not any significant relationship between crime and what are popularly believed to be its 'causes'—inherited stigma, poverty, neglect, illiteracy, &c. In other words, there are no physical, mental, or moral characteristics peculiar to the inmates of English prisons. What Dr. Goring insists upon is that conviction of crime is associated with constitutional rather than circumstantial conditions, and, as these are heritable, the genesis of crime must to this extent be influenced by heredity; and the criminal diathesis, revealed by the tendency to crime, is affected by heredity to much the same extent as other physical and mental conditions in man; but this does not mean that a man is predestined to a criminal career by a tendency which he is unable to control. It only means that heritable constitutional conditions have hitherto prevailed in the making of criminals; which is to say, that variation of environment within the restricted limits examined (from the education of the streets to that of public elementary school, reformatory school, &c., for instance) has not been sufficient, in the long run, to counteract or mask the force of inherited proclivity, which nevertheless is itself a force of varying intensity, and one which can be regulated, encouraged, or stultified by training and education and example."

Constitution of the Commission.

The following reference is made to the recent change in the constitution of the Commission by the appointment of Sir Herbert Smalley to be a member of the board: "The growing importance of the medical side of prison administration, the numberless questions that continually arise demanding medical knowledge and experience, led the Secretary of State to the opinion that there should be a strengthening of this Commission by the addition of a medical authority of long and wide experience, and one who, as medical inspector for many years, had become conversant with all questions affecting the mental and physical state of prisoners. Sir H. Smalley now takes his place on the Prisons Board, and will be relieved to a large extent of the duties of general inspection which he has hitherto discharged by the appointment of Mr. O. F. N. Treadwell, formerly medical officer of Parkhurst Prison, to be Assistant Medical Inspector of Prisons."

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

THE undermentioned Lieutenants are confirmed in their rank:—Ernest W. Wade, Bernard Woodhouse, William K. Morrison, Edgar Percival, Stanley J. Linzell, and Lewis R. Shore.

The undermentioned to be temporary Lieutenants:—Dated Oct. 5th: Edmund Rupert Dermer, Godfrey Martin Huggins, Charles Matheson Kennedy, Charles Dudley Roberts, James Heslop Aikman, Delvine Bell, Edwin Brace Barton, John Smith Knox Boyd, Douglas Morris Borland, Dudley Thomas Birt, Alan Willis Gaye, William Sim Garden, John Hugh Cuthbert Green, Aubrey Goodwin, Stanley Honeyman, Alfred Ernest Hallinan, Thomas Hugh Houston, Robert McCowan Hill, William Christopher Jardine, Courtnay Cooper Keates, James William Littlejohn, David Matthew, William Stretley Martin, Daniel McVicker, Henry Maurice MacKenzie, Fred Wallace Mackenzie, John Tertius Morrison, Hugh London Neil, Ralph Stransham Oldham, William Berwick Ure Patterson, George Rankine, John Symington Stewart, William Robertson Snodgrass, James John Sinclair, Neil Frederick Sinclair, James Taylor, James Herbert Grove-White, and Donald Wainwright.

SUPPLEMENTARY TO REGULAR UNITS OR CORPS.

Lieutenant Philip S. Vickerman is granted seniority as from April 8th.

ROYAL NAVAL VOLUNTEER RESERVE.

A temporary commission has been issued to J. Westwood [illegible] Surgeon.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants to be Captains: Paul B. Roth, Laurence M. Routh, James O. Hamilton, Charles A. Bignold, Keith B. MacGlashan, John Adams, Leonard W. O. Taylor, James B. Williamson, Claude Johnson, Gilbert K. Aubrey, Henry H. Brown, and John Fraser.

The undermentioned Lieutenants are confirmed in their rank:—Francis R. H. Mollan and James O'Brien.

The undermentioned Cadets of the Officers Training Corps to be Lieutenants (on probation): Frederick John Henry Tobias Frere and Roderic Duncan Cameron.

The undermentioned to be Lieutenants (on probation): Colin Grant, Lionel Arthur Lewis, and Neale Leo Lochrane.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st East Anglian Field Ambulance: George James Leask to be Quartermaster, with the honorary rank of Lieutenant. Harry Harris to be Transport Officer, with the honorary rank of Lieutenant.

3rd East Anglian Field Ambulance: Frederick Claude Kempson to be Lieutenant.

1st Highland Field Ambulance: The undermentioned to be Lieutenants: Charles Alexander Whyte and George Davidson. James Dickie to be Quartermaster, with the honorary rank of Lieutenant.

3rd Highland Field Ambulance: John Morrison Milne to be Lieutenant.

1st Home Counties Field Ambulance: William Brooks Keith to be Lieutenant.

1st West Lancashire Field Ambulance: The undermentioned Captains to be Majors: Creighton H. Lindsay and Adam P. H. Simpson.

3rd West Lancashire Field Ambulance: The undermentioned Captains to be Majors: Augustus A. W. Merrick and Richard Coffey.

1st Northumbrian Field Ambulance: Roger Errington to be Lieutenant.

2nd Northumbrian Field Ambulance: Major Duncan Alexander Cameron to be Lieutenant-Colonel. Captain Duncan Vercoe Haig and Captain David Leonard Fisher to be Majors. Valentine Hutchinson Wardle (late Cadet, Durham University Contingent, Senior Division, Officers Training Corps) to be Lieutenant. Angus Ferens to be Transport Officer, with the honorary rank of Lieutenant.

1st London (City of London) General Hospital: Arnold Walmsley Stott to be Lieutenant. The undermentioned to be Lieutenants (dated Sept. 5th): Alfred Bernard Pavey Smith, Lionel Gordon Crossman, and Martin Wright Kidman Bird.

2nd London General Hospital: The undermentioned to be Lieutenants: Cyril Eaton Petley, Leonard Milton, Herbert Sharpe, and Hubert John Burgess Fry.

3rd London General Hospital: The undermentioned to be Lieutenants: George Harvey Duder Webb, John St. Andrew Titmas, Harry Audley Lucas, and Edward Smeed.

4th London General Hospital: Major Stanley Boyd to be Lieutenant-Colonel.

5th Southern General Hospital: The announcement notifying the resignations of Lieutenant-Colonel and Honorary Surgeon-Colonel George G. Sparrow and Lieutenant-Colonel John R. S. Robertson is cancelled.

South Wales Mounted Brigade Field Ambulance: The undermentioned to be Lieutenants: Guy Starkey Thompson, Archibald John Campbell, and Ernest Littleton Sandiland.

3rd Welsh Field Ambulance: William Jones Richards to be Lieutenant.

3rd Wessex Field Ambulance: Captain Elliott B. Bird to be Major.

2nd Eastern General Hospital: Major James A. Rooth to be Lieutenant-Colonel. Lieutenant Hugh M. Galt, from Attached to Units other than Medical Units, to be Captain.

Supernumerary for Service with the Officers Training Corps: Andrew Daniel Clinch to be Lieutenant, for service with the Dublin University Contingent, Senior Division, Officers Training Corps.

Attached to Units other than Medical Units.—Major William Kirman Pauli, from the Territorial Force Reserve, to be Major. Major Herman Stedman resigns his commission, and is granted permission to retain his rank and wear the prescribed uniform. Captain Charles Arthur Morris, C.V.O., to be Major. Supernumerary Captain Matthew B. Ray is absorbed into the establishment. Lieutenant Angus McNab and Lieutenant Alan C. Ransford to be Captains. Thomas Vicars Oldham, James Gerald Fayrer Hosken, and Edward Lister Martin to be Lieutenants. Lieutenant Norman M. Fergusson to be Captain. Lieutenant Robert W. Simpson to be Captain. John Forbes Ward to be Lieutenant. John James Scanlan (late Surgeon-Captain 35th Imperial Yeomanry) to be Lieutenant.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on Oct. 13th, Surgeon-General Sir Arthur W. May, K.C.B., in the chair, the sum of £40 was distributed among the several applicants.

DEATHS IN THE SERVICES.

Lieutenant-Colonel Herbert Wilson Pilgrim, recently, at Brighton, aged 56. He joined the Indian Medical Service in 1886, reaching the rank of lieutenant-colonel in 1906. In 1892 he was appointed resident surgeon at the Presidency General Hospital, Calcutta, and in 1898 surgeon-superintendent.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 97 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8052 births and 4653 deaths were registered during the week ended Saturday, Oct. 17th. The annual rate of mortality in these towns, which in the three preceding weeks had been 15·7, 14·3, and 13·9 per 1000 of their aggregate population, estimated at 18,120,059 persons at the middle of this year, further declined to 13·4 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 13·2, against a corresponding rate of 13·3 per 1000 in London. Among the several towns the death-rate last week ranged from 5·9 in Ealing, 6·2 in Southend-on-Sea, 6·3 in Ilford, 6·4 in Hornsey, 6·9 in Lincoln, and 7·3 in Walthamstow and in Bolton, to 18·2 in Liverpool and in Wigan, 18·4 in Barnsley, 19·2 in Rotherham, 19·7 in Gateshead, 20·6 in Middlesbrough, and 23·1 in Dewsbury.

The 4653 deaths from all causes were 194 fewer than the number in the previous week, and included 529 which were referred to the principal epidemic diseases, against numbers declining from 1437 to 710 in the four preceding weeks. Of these 529 deaths, 322 resulted from infantile diarrhœal diseases, 67 from measles, 59 from diphtheria, 38 from whooping-cough, 29 from scarlet fever, and 14 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·5, against 2·0 per 1000 in the previous week. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had declined from 1223 to 485 in the four preceding weeks, further fell to 322, and included 91 in London, 32 in Liverpool, 19 in Birmingham, 14 in Manchester, and 7 in Middlesbrough. The deaths referred to measles, which had been 50, 61, and 73 in the three preceding weeks, fell to 67 last week, of which 21 were registered in London, 9 in Liverpool, 6 in Birkenhead, 5 in Birmingham, and 3 each in Manchester, Wigan, and Oldham. The fatal cases of diphtheria, which had been 56, 63, and 57 in the three preceding weeks, were 59 last week, of which 16 occurred in London, 5 in Birmingham, 4 in Portsmouth, and 3 in Manchester. The deaths attributed to whooping-cough, which had been 40, 50, and 47 in the three preceding weeks, further declined to 38 last week, and included 13 in London, 3 in Rhondda, and 2 in Acton. The deaths referred to scarlet fever, which had been 23, 29, and 31 in the three preceding weeks, fell to 29 last week, of which 6 were recorded in London, 3 each in Manchester and Newcastle on-Tyne, and 2 each in Southampton, Salford, and Sheffield. The fatal cases of enteric fever, which had been 16, 23, and 17 in the three preceding weeks, fell to 14 last week, of which 2 each occurred in London and Liverpool.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily increased from 3071 to 4363 in the eight preceding weeks, had further risen to 4473 on Saturday last; 650 new cases were admitted during the week, against 674, 640, and 670 in the three preceding weeks. These hospitals also contained on Saturday last 1443 cases of diphtheria, 71 of enteric fever, 34 of whooping-cough, and 30 of measles, but not one of small-pox. The 1205 deaths from all causes in London were 13 in excess of the number in the previous week, and corresponded to an annual rate of 13·9 per 1000. The deaths referred to diseases of the respiratory system, which had increased from 110 to 175 in the four preceding weeks, further rose to 178 in the week under notice, and were 2 above the number in the corresponding week of last year.

Of the 4653 deaths from all causes in the 97 towns, 182 resulted from various forms of violence, and 357 were the subject of coroners' inquests, while 1424 occurred in public institutions. The causes of 26, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Leeds, Bristol, Hull, Newcastle-on-Tyne, and in 58 other smaller towns. Of the 26 uncertified causes of death, 5 were registered in Birmingham, 3 in Gateshead, and 2 in Smethwick.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,293,200 persons at the middle of this year, 1128 births and 646 deaths were registered during the week ended Saturday, Oct. 17th. The annual rate of mortality in these towns, which had been 16·3, 15·6, and 15·9 per 1000 in the three preceding weeks, declined to 14·7 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 14·4, against 13·2 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 4·1 in Hamilton, 8·5 in Coatbridge, and 8·8 in Kilmarnock, to 15·3 in Glasgow, 16·9 in Edinburgh and in Dundee, and 18·7 in Greenock.

The 646 deaths from all causes were 52 fewer than the number in the previous week, and included 81 which were referred to the principal epidemic diseases, against 92 and 96 in the two preceding weeks. Of these 81 deaths, 29 resulted from infantile diarrhœal diseases, 19 from diphtheria, 16 from scarlet fever, 10 from whooping-cough, 6 from enteric fever, and 1 from measles, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·8, against 1·5 per 1000 in the 97 English towns. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 87, 52, and 54 in the three preceding weeks, declined to 29, of which 13 were registered in Glasgow and 3 each in Edinburgh, Dundee, and Paisley. The deaths referred to diphtheria, which had increased from 4 to 14 in the four preceding weeks, further rose to 19 last week, and comprised 8 in Edinburgh, 5 in Glasgow, 5 in Aberdeen, and 1 in Leith. The fatal cases of scarlet fever, which had been 12, 12, and 13 in the three preceding weeks, rose to 16 last week, and included 9 in Glasgow, 3 in Paisley, 2 in Edinburgh, and 2 in Aberdeen. The deaths attributed to whooping-cough, which had been 13, 13, and 8 in the three preceding weeks, rose to 10 last week, of which 8 were recorded in Glasgow. The deaths referred to enteric fever, which had been 4, 4, and 6 in the three preceding weeks, were again 6 last week, and comprised 4 in Glasgow and 2 in Edinburgh. The fatal case of measles occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had increased from 62 to 84 in the four preceding weeks, further rose to 89 in the week under notice; 29 deaths resulted from different forms of violence, against 27 and 28 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,205,280 persons at the middle of this year, 546 births and 375 deaths were registered during the week ended Saturday, Oct. 17th. The annual rate of mortality in these towns, which had declined from 19·9 to 15·4 per 1000 in the four preceding weeks, rose to 16·2 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 16·9, against corresponding rates of 13·2 and 14·4 per 1000 in the English and Scotch towns respectively. The annual death-rate last week was equal to 17·0 in Dublin (against 13·9 in London and 15·3 in Glasgow), 17·3 in Belfast, 19·0 in Cork, 10·1 in Londonderry, 17·6 in Limerick, and 17·1 in Waterford, while in the 21 smaller towns the mean death-rate did not exceed 12·8 per 1000.

The 375 deaths from all causes were 20 in excess of the number in the previous week, and included 57 which were referred to the principal epidemic diseases, against 53 in each of the two preceding weeks. Of these 57 deaths, 33 resulted from infantile diarrhœal diseases, 7 from measles, 7 from scarlet fever, 4 from diphtheria, 3 from whooping-cough, and 3 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·5, against corresponding rates of 1·5 and 1·8 per 1000 in the English and Scotch towns respectively. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had declined from 74 to 34 in the four preceding weeks, were 33 last week, of which 12 were recorded in Belfast, 10 in Dublin, 5 in Cork, and 3 in Limerick. The 7 deaths referred to measles were registered in Belfast, and were 3 in excess of the average in the four preceding weeks. The fatal cases of scarlet fever, which had been 2, 2, and 4 in the three preceding weeks, further rose to 7 last week, and included 3 in Belfast and 2 in Waterford. The 4 deaths attributed to diphtheria, of which 2 occurred in Dublin, were double the average in the four preceding weeks. The 3 fatal cases of enteric fever were registered in Dublin, and those of whooping-cough in Belfast.

The deaths referred to diseases of the respiratory system, which had been 56, 58, and 56 in the three preceding weeks, rose to 71 in the week under notice. Of the 375 deaths from all causes, 102, or 27 per cent., occurred in public institutions, and 5 resulted from different forms of violence. The causes of 8, or 2·1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 97 English towns the proportion of uncertified causes of death last week did not exceed 0·6 per cent.

VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1914.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 11·6 per 1000 of the population, estimated at 4,516,612 persons in the middle of the year; in the three preceding months the rates were 7·6, 7·8, and 7·5 per 1000 respectively. The lowest rates last month were recorded in Chelsea, St. Marylebone, Hampstead, Hackney, Holborn, and Wandsworth; and the highest rates in Fulham, Islington, Bethnal Green, Stepney, Poplar, and Deptford. Scarlet fever was much more prevalent than it had been in any preceding month of this year; the greatest proportional prevalence of this disease last month was recorded in Hammersmith, Islington, Stoke Newington, the City of London, Bethnal Green, and Stepney. The Metropolitan Asylums Hospitals contained 4157 scarlet fever patients at the end of last month, against 3045, 3113, and 3199 at the end of the three preceding months; the weekly admissions averaged 598, against 396, 410, and 414 in the three preceding months. Diphtheria also was excessively prevalent as compared with other recent months; this disease was proportionally most prevalent last month in Bethnal Green, Stepney, Poplar, Deptford, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1080, 1042, and 1030 at the end of the three preceding months, had risen again to 1296; the weekly admissions averaged 188, against 131 and 128 in the two preceding months. Enteric fever was proportionally more prevalent than it had been in any month since February; among the several metropolitan boroughs this disease was proportionally most prevalent in Chelsea, the City of Westminster, St. Marylebone, Holborn, Greenwich, and Woolwich. There were 57 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 40, 36, and 39 at the end of the three preceding months; the weekly admissions averaged 11, against 8, 6, and 7 in the three preceding months. Erysipelas was proportionally most prevalent in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Bermondsey, Deptford, and Greenwich. The 41 cases of puerperal fever notified during the month included 5 in Islington, 4 in Fulham, 3 in St. Pancras, 3 in Southwark, and 3 in Camberwell. The 10 cases of cerebro-spinal meningitis included 2 in Islington and 2 in Stepney; and the 31 cases of poliomyelitis included 12 in Stepney, 5 in Poplar, 3 in Hackney, and 2 each in Southwark, Lambeth, and Camberwell.

The mortality statistics relate to the deaths of persons

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the population of the several boroughs. During the five weeks ending Oct. 3rd the deaths of 6703 London residents were registered, equal to an annual rate of 15·5 per 1000; in the three preceding months the rates had been 12·6, 11·3, and 12·6 per 1000 respectively. The death-rates last month ranged from 9·6 in Hampstead, 9·8 in Lewisham, 11·6 in the City of Westminster, 11·8 in Wandsworth, 12·1 in the City of London, and 12·4 in Hammersmith, to 19·0 in Stepney, 19·2 in Bethnal Green, 20·1 in Bermondsey, 20·6 in Southwark, 21·0 in Poplar, 21·9 in Finsbury, and 25·8 in Shoreditch. The 6703 deaths from all causes included 1659 which were referred to the principal infectious diseases; of these, 115 resulted from measles, 36 from scarlet fever, 72 from diphtheria, 79 from whooping-cough, 15 from enteric fever, and 1342 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Kensington, the City of Westminster, St. Marylebone, Hampstead, and Woolwich; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Poplar, Southwark, and Bermondsey. The 115 fatal cases of measles were 59 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal last month in Islington, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Battersea. The 36 cases of scarlet fever were 20 above the average number; the greatest proportional mortality from this disease was recorded in Kensington, Fulham, Chelsea, Stepney, and Lambeth. The 72 deaths from diphtheria exceeded the average by 29, the greatest proportional mortality being recorded in St. Pancras, Hackney, Poplar, Bermondsey, Lambeth, Deptford, and Woolwich. The 79 fatal cases of whooping-cough were 15 above the corrected average number; this disease was proportionally most fatal in Paddington, Finsbury, Shoreditch, Stepney, Southwark, and Camberwell. The 15 deaths from enteric fever were 4 below the corrected average, and included 2 in Stepney and 2 in Poplar. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Bermondsey, and Deptford. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was 60·1 per cent. above the average.

DONATIONS AND BEQUESTS.—By will the late Miss Margaret Harker Smith, of Holmbrook, Tunbridge Wells, Kent, has left £10,000 to the Homœopathic Hospital, Tunbridge Wells, £6000 to the University College Hospital for the Cancer Research Fund, and £5000 to the New Hospital for Women, London.—The late Mr. John Sykes, of Huddersfield, has bequeathed £2000 to the Huddersfield Royal Infirmary.—The Leicester Infirmary will receive £500 under a bequest of the late Mr. Alfred Green.

A POINT AS TO MILK ADULTERATION.—In Scotland Sheriff Shennan gave judgment recently at Hamilton on a point arising out of milk adulteration. It was proved by the evidence of inspectors who were eye-witnesses that some new milk was in fact adulterated by being poured into cans in which a certain quantity of skimmed milk had already been placed. The milk thus mixed was then purchased by the inspectors as a sample of "sweet milk" from the dealer on whose premises the mixing took place. For the defence it was contended that as the admixture of skimmed milk had not lowered the proportion of milk fat in the article as sold below the 3 per cent. standard fixed as a minimum by the Board of Agriculture there was no offence, and that as the inspectors had seen the mixing take place they had notice of it. Sheriff Shennan convicted the dealer, holding that to diminish the proportion of milk fat in the milk by 15 per cent. was to affect the milk injuriously and injure the purchaser, and that the Food and Drugs Act was not meant to legalise the thinning down of rich milk to the minimum. The purchaser was entitled to notice if any such alteration took place, and the fact that the inspectors knew of it did not absolve the seller from the duty to give such notice. He inflicted a fine of £5.

"Audi alteram partem."

THE NURSING OF THE WOUNDED.

To the Editor of THE LANCET.

SIR,—It has been brought to the notice of the committee of the British Red Cross Society that doctors in various parts of the country are complaining that wounded soldiers are, as they allege, being nursed by members of Voluntary Aid Detachments, who are not fully trained and certificated nurses.

On behalf of this society I desire to point out that no offer of hospital accommodation which has been submitted to us, and has been approved of by the military authorities, is ever accepted unless fully trained and certificated nurses are in charge. In these hospitals the services of Voluntary Aid Detachments are utilised as probationers, cooks, and in other general ways.

If hospitals are started and utilised by the military authorities without reference to this society the doctor who is asked to take medical charge should, if he finds lack of skilled nurses, apply to the authority responsible for starting such a hospital.

I may mention that we have upon our books the names of some 1500 trained and fully certificated nurses whose services could be called upon at any time in case of need and without expense to the hospitals for which they are required.

I am, Sir, yours faithfully,
ARTHUR STANLEY,
Chairman of the Executive Committee.
83, Pall Mall, London, S.W., Oct. 19th, 1914.

THE MEDICAL REGISTER.

To the Editor of THE LANCET.

SIR,—May I once more ask you for your valuable assistance in reminding members of the profession that unless their names appear in the Medical Register they are not "legally qualified medical practitioners" (Medical Act, 1858, Section 34), and that the duty of notifying changes of address rests with them.

> No person can "hold any appointment as a physician, surgeon, or other medical officer either in the military or naval service or in emigrant or other vessels, or in any hospital, infirmary, dispensary, or lying-in hospital, not supported wholly by voluntary contributions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poor-house, parish union, or other public establishment, body, or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age, or as a medical officer of health, unless he be registered" (Section 36); and "no certificate required by any Act now in force, or that may hereafter be passed, from any physician, surgeon, licentiate in medicine and surgery, or other medical practitioner, shall be valid unless the person signing the same be registered" (Section 37).

The Medical Register is the only official publication, and should not be confused with any of the various directories which issue circulars annually.

No one who is not familiar with the work of this office would believe the amount of trouble which is taken to keep in touch with practitioners, and to find them when touch has been lost; but unless we are assisted by members of the profession ourselves our efforts are often fruitless. In consequence of cases which have recently occurred it becomes increasingly important every year that the registrar should carry out the duty laid upon him under Section 14 of removing from the Register the names of practitioners with whom he cannot communicate. It is done with reluctance, but only by this means can the public and the profession be protected against impostors. No doubt cases of hardship do sometimes arise in consequence of this removal of names, but every possible source of information is made use of to save practitioners from the results of their own forgetfulness, and if they are inconvenienced by finding that their names are off the Register the blame does not rest with this office.

Perhaps I may add that by a recent regulation practitioners possessing medical and dental qualifications, if already on the Medical Register, may register in the Dentists Register (or *vice versâ*) for a reduced fee of £2 1*s*. instead of £5 1*s*. I should also like to take the opportunity of drawing attention to the following resolution adopted by the Council on Nov. 30th, 1911, and re-drafted on June 1st, 1914. It cannot be too strongly urged upon practitioners that in giving certificates they are recognised by law as members of a trusted profession, and that it behoves them to exercise the greatest possible care in the matter:—

CERTIFICATES, NOTIFICATIONS, REPORTS, ETC.

Registered practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates, notifications, reports, and other documents of a kindred character, signed by them in their professional capacity, for subsequent use either in Courts of Justice or for administrative purposes. Such documents include, among others, certificates, notifications, reports, &c.: (*a*) Under the Statutes relating to births, deaths, or disposal of the dead; (*b*) under the Acts relating to lunacy and mental deficiency and the rules made thereunder; (*c*) under the Vaccination Acts and the Local Government Board Orders made thereunder; (*d*) under the Factory Acts and the Home Office Regulations made thereunder; (*e*) under the Education Acts; (*f*) under the Public Health Acts and the Local Government Board Orders made thereunder; (*g*) under the Workmen's Compensation Acts; (*h*) under the Acts and the Local Government Board Orders relating to the notification of infectious diseases; (*i*) under the National Insurance Acts and the regulations made thereunder; (*j*) under the Old Age Pensions Acts and the Treasury Regulations made thereunder; (*k*) under the Merchant Shipping Acts; (*l*) in connexion with sick benefit, insurance, and Friendly Societies; (*m*) for procuring the issue of Foreign Office passports; (*n*) for excusing attendance in courts of justice, in the public services, in public offices, or in ordinary employments; (*o*) in connexion with naval and military matters.

Any registered practitioner who shall be shown to have signed or given under his name and authority any such certificate, notification, report, or document of a kindred character, which is untrue, misleading, or improper, *whether relating to the several matters above specified or otherwise*, is liable to have his name erased from the Register.

I am, Sir, yours faithfully,
A. J. COCKINGTON,
Acting Registrar.
General Council of Medical Education and Registration of the United Kingdom, Oxford-street, London, W., Oct. 15th, 1914.

MULTIPLE ROUND-CELLED SARCOMA.

To the Editor of THE LANCET.

SIR,—Will you allow me to draw the attention of your readers to the case of multiple round-celled sarcoma, so clearly reported by Mr. C. N. Slaney, of Parkhurst Convict Prison, in to-day's issue of THE LANCET. I had opportunities of seeing the patient several times with Mr. Slaney and with Mr. O. F. N. Treadwell (then senior medical officer at the prison), and, deeming the case to be of very exceptional interest and rarity, I subsequently showed Mr. Slaney's notes of the clinical history and the necropsy to some expert pathologists, including Dr. R. G. Hebb, who considered them of importance as demonstrating a very rare example of this particular form of growth. I am informed that specimens from the case, which at Mr. Treadwell's request were kindly examined by Mr. Shattock and Mr. Dudgeon, will be preserved in the museum of St. Thomas's Hospital.

I am, Sir, yours faithfully,
London, Oct. 17th, 1914.   H. BRYAN DONKIN.

IMPERFECTIONS IN THE CUMBERLAND INFIRMARY.

To the Editor of THE LANCET.

SIR,—Mr. H. A. Lediard's letter in THE LANCET of Oct. 17th carries this matter no further. My report is one of some hundreds which are to be republished collectively, and each faithfully records the condition of each hospital as I found it when compared with the standard of an up-to-date modern hospital.

The letter contains innuendoes which relate to matters of which I am without information, and so an apology is called for to myself. Also certain statements which exhibit a surprising disregard of official facts open to the governors—to wit, the annual report for 1914 states on a slip attached to its cover that "there is accommodation for 150 in-patients." 140 of these beds were reported to be available. I was informed that the small room provided for the laundry-maids was used by 11 not 4 persons as stated by Mr. Lediard. A clinical room is an essential part of the ward unit of every up-to-date hospital where the treatment and medical work are modern and efficient. Every properly organised voluntary hospital has a mortuary chapel or view room so that reverence for the dead and due consideration for the living may always be secured.

Mr. Lediard's letter confirms me in the opinion that an independent inquiry in the form I suggested is desirable if the governors wish the administration and efficiency of the Cumberland Infirmary to be brought to the standard of a modern hospital. Each city has the hospital it deserves. Whether its standard of efficiency is high or low rests with the citizens.

I am, Sir, yours faithfully,
HENRY C. BURDETT.
Porchester-square, W., Oct. 19th, 1914.

THE TREATMENT OF TETANUS.

To the Editor of THE LANCET.

SIR,—Anything which may be of use to our wounded needs no apology; therefore I wish to repeat some remarks I made in the *British Medical Journal* of Nov. 5th, 1910.

In the ordinary way tetanus is such a rare disease that it only occupies a small part of one's thoughts. This is not the case now. Tetanus kills partly by the direct action of the toxin and partly by the exhausting effect of the convulsions. By the trismus, and dread that taking food will bring on a convulsion, starvation is added to the horrors of the disease, and sleep is prevented by the painful muscular contractions. In treating the disease when it is manifest there are therefore the following indications: 1. To prevent further absorption of toxin by the removal of its source as far as possible. 2. To neutralise the toxin present.

3. To relax the muscles and prevent the tetanic spasms so that the patient will escape the exhaustion and be able to take food and to sleep. Consequently he will be spared much suffering and be in the best position to fight the disease. Of the first two indications the necessity for removing every scrap of necrotic tissue or blood clot, the provision of the freest drainage, the great value of the prophylactic dose of antitetanus serum after suspicious wounds, and the necessity for large doses to produce effect when the disease is established, are too well known to need more than passing mention. But the use of chloretone to meet the third indication does not seem as well known as it deserves.

McClintock and Hutchins undertook an experimental study of the various drugs used for this purpose, and were convinced that chloretone was the best and least poisonous substance hitherto employed. Hutchins published six cases treated with chloretone with four recoveries. The only case I have so treated was a severe one; the beneficial effects of the drug were immediate and striking; trismus was almost abolished and convulsions completely prevented, and the patient recovered. These cases seem more than to warrant a further trial of chloretone. The method of using chloretone is as follows: 30 to 40 grains of chloretone in olive oil are given per rectum; in one or two hours there should be an improvement in the muscular symptoms. When the effect passes off the dose is repeated. Our man had an average of 80 grains a day for five days. Chloretone poisoning is by respiratory failure, so this must be looked out for. Its use is in no way to supersede antitoxin or surgical measures, but to act as a very useful ally. I am, Sir, yours faithfully,

Guildford, Oct. 10th, 1914. ERIC W. SHEAF.

IN THE TRAIL OF WAR.

To the Editor of THE LANCET.

SIR,—The Local Government Board has issued a timely warning to medical officers of health as to watching during the period of war for the occurrence of typhus, enteric, and small-pox. (THE LANCET, Oct. 17th, 1914, p. 951.) In a war of long duration, having regard to present conditions in the eastern sphere of operations, to this list, later on, may perhaps be added cholera. In the meantime antityphoid vaccine is being energetically prepared for the troops; but, so far, no information is available to the public that special precautions are being made to have ready a stock of anti-small-pox animal vaccine both for the troops and the civil population (*plus* refugees) in excess of normal demands. Its production requires time and the employment of calves within particular age limits, and it might be when small-pox appears bovines generally would not be so readily procurable as at present. It would, therefore, seem reasonable to ice-store a reserve for prompt action.

At the risk of being crushed by the cry of "there is nothing like leather," I suggest that in the favouring of duration of vitality without the aid of ice, meeting conditions of rough transport and of use of variable quantities for scattered groups of men, lanolinated vaccine in collapsible tin tubes is more suitable than either glycerinised or dried vaccine. As an instance of its convenience for rapid work I may state that during a small-pox scare in 1891, at Bangalore, by arranging that the men with already cleansed arms marched past me, with the aid of three assistants to hand sterilised instruments, &c., I vaccinated 1000 British and Indian troops in one day. I am, Sir, yours faithfully,

W. G. KING,
Hatch End, Middlesex, Oct. 14th, 1914. Colonel, I.M.S. (retired).

PREVENTION AND TREATMENT OF CHAFES BY BOOTS.

To the Editor of THE LANCET.

SIR,—For the prevention of sore feet during the march I can strongly recommend from personal experience soaking the uppers of the boots with castor oil and pouring a little of this oil on the feet, especially between the toes, and then putting on thick socks and the soaked boots.

When abrasions appear between the toes, wrapping a small piece of cotton or linen soaked in castor oil round each toe entirely removes the pain of a slight chafe and enables the sufferer to resume his walk with comfort. Ordinary hot drawn engine-room castor oil is just as efficacious as cold drawn for application to the feet and boots, and is of course much cheaper.

The great importance of preventing or mitigating the sufferings from boot chafe at the present time is my sole excuse for trespassing on your valuable space. I am, Sir, yours faithfully,

A. R. S. ANDERSON, M.B. Cantab.,
Dacca, Sept. 16th, 1914. Lieutenant-Colonel, I.M.S.

WANTED, A DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—I should be very grateful if any of your readers could give me any suggestions regarding the nature of the two following cases. Both patients were Wachuka (a native tribe of British East Africa) and fairly intelligent, though, on account of difficulties of language, not easy to examine.

The first, aged about 20 years, was admitted to hospital on March 10th, 1914, having been taken ill the day before. I was not able to ascertain the nature of the first symptoms. When first seen he showed weakness of both legs and was quite unable to stand. There was difficulty in sitting up, owing apparently to weakness of the muscles of the back and abdomen, the iliopsoas, and the glutei. The various groups of muscles in the legs were equally affected and both legs displayed the same loss of power. When lying flat he could raise either leg from the bed and flex and extend the knee- and ankle-joints, but all movements were overcome by slight resistance. All reflexes in the legs, superficial and deep, were lost. There was no loss of power in the arms and none of the muscles supplied by cranial nerves were affected. The abdominal, epigastric, and cremasteric reflexes were absent. In the arms all tendon reflexes were obtained. The palate reflex was present.

Very careful examination failed to reveal any impairment of sensation. The next day the weakness of the legs had increased, and there was considerable loss of power in the arms. The tendon reflexes of the arms were obtained with difficulty.

Hereafter there followed a progressive loss of power in the arms, legs, and trunk, until in four or five days from the onset of the disease the patient was absolutely paralysed save for the facial, orbital, and tongue muscles. The sterno-mastoid and other neck muscles retained some power so that the head could be lifted from the bed, but not against slight resistance. Deglutition was not interfered with. There was slight loss of control of the bladder, the patient occasionally passing urine involuntarily for some days, but in less than a week this ceased and normal control was regained. There was never any incontinence of fæces. With the onset of complete paralysis respiration became entirely diaphragmatic, but with recovery costal respiration gradually returned. At no time during the disease was there any sensory loss, either of light touch, heavy pressure, or heat and cold. The result of the "compass point" test was always normal throughout the disease, and the sense of stereognosis was also unimpaired. At times slight pain was complained of in arms and legs, but it was always of brief duration, and often there was no pain for days together. The pupils remained normally active throughout, and I was unable to detect any change in the fundi oculorum, though lack of a suitable lamp made this examination very difficult. The patient's want of intelligence, or the deficiencies in my knowledge of his language, rendered even a rough charting of his visual fields an impossibility. There has never been any rise of temperature, and the pulse has varied between 75 and 85. For a month or five weeks there was no change in the patient's condition except for the return of power to the sphincter of the bladder within a few days of its loss. Since this time there has been a very slow but steady return of power, most marked in the arms.

The condition on August 1st, 1914, was as follows. The arms are weak, but the patient is perfectly capable of feeding himself and lifting light articles. There is no incoördination, even such fine movements as picking up a pin being rapidly and easily performed. The tendon reflexes in the arms are with difficulty obtainable and are absent in the legs. The neck muscles are slightly weaker than normal, as also are those of the trunk, but there is no difficulty in rising to a sitting posture and in maintaining it. The legs still remain very weak and the patient is quite unable to stand even with support, but either leg can be raised when the patient is lying down, and the knee- and ankle-joints can be weakly flexed and extended. He is able to move about slowly by sitting down and "walking on his hands"—i.e., raising the trunk from the ground and heaving the buttocks forward. What incoördination there is appears to be due to weakness rather than loss of muscle sense. All through the disease there has been very little wasting of the muscles, certainly not more than can be accounted for by disuse. The arms are now as well developed as when the patient was first seen, and the legs are quite well formed.

The second case closely resembles the first, differing only in the more complete recovery. The patient, a native, aged about 14 years, was admitted early in April of this year complaining of general pains which appeared to be rheumatic in nature. Two days after weakness of the limbs became apparent, with loss of reflexes, and in six days from the onset of symptoms there was complete paralysis of all except the facial and orbital muscles and those of mastication and deglutition. His condition exactly resembled that of the first case, except that there was never any loss of sphincter control and more pain was complained of in the limbs. After three weeks of complete paralysis a gradual recovery commenced, and by the middle of June he was able to walk with the aid of a stick. The arms regained power rather more rapidly than the legs. At the present time he can walk well unaided and is able to do light work.

In neither case was there any "blue line" on the gums or any suspicion of the patient having been exposed to lead. Previous to the onset of disease both patients had been engaged in stone-breaking for about two months—i.e., since they left their own country—and their food had been similar to that given to the rest of the native labour, mainly rice, Jugo beans, and various kinds of meal. Meat was rarely eaten, and fresh vegetables never. The only treatment given was the administration of perchloride of mercury and potassium iodide.

I am, Sir, yours faithfully,
E. NORMAN BUTLER,
Medical Officer-in-Charge, Magadi Railway, British East Africa.

THE WAR.

MEDICAL HEADQUARTERS STAFF APPOINTMENTS.

Mr. Fréderic F. Burghard, surgeon to King's College Hospital, has been appointed consulting surgeon to the Forces, and left for France on Wednesday morning to enter upon his new duties.

Sir Wilmot Herringham, Sir John Rose Bradford, and Sir Almroth Wright, whose appointment as consulting physicians to the Forces Overseas was announced in our last issue, left England on Wednesday to take up their duties with the Expeditionary Army in France, where they will hold the rank of Colonel in the Army Medical Service. We understand that Sir John Rose Bradford will be accompanied by Dr. T. R. Elliott, F.R.S., assistant physician to University College Hospital, and Sir Almroth Wright by Dr. Alexander Fleming.

MENTIONED IN DESPATCHES.

The following names of officers in the Royal Army Medical Corps have been brought forward in his recently published despatches by Field-Marshal Sir John French for special mention for services in the field from the beginning of the present campaign up to Oct. 8th:—

General Headquarters Staff.

Cummins, Major S. L.
Woodhouse, Surgeon-General T. P. (temporary).
Birrell, Major E. T. F.
Bourdillon, Lieutenant L. G.
Butler, Major S. G.
Caddell, Captain E. D.
Cowey, Major R. V.
Dolbey, Lieutenant R. V.
Ensor, Major H., D.S.O.
Fielding, Major T. E.
Foster, Major R. L. V.
Grech, Major J.
Goodwin, Major T. H. J. C., D.S.O.
Hairsine, Lieutenant C. (Special Reserve).
Helm, Lieutenant C.
Hinge, Major H. A.
Hopkins, Lieutenant H. L. (Civil Surgeon) (killed).
Howells, Lieutenant W. M.
Huggan, Lieutenant J. L. (killed) (attached 3rd Battalion Coldstream Guards).
Kempthorne, Captain G. A. (attached 1st Battalion Lincolnshire Regiment).
Lathbury, Captain E. B.
Leckie, Captain M. (attached 1st Battalion Northumberland Fusiliers).
Lewis, Captain S. E. (attached 2nd Battalion Royal Irish Rifles).
Lloyd, Major O. W.
McEntire, Captain J. T.
Mitchell, Lieutenant-Colonel L. A.
Morgan, Lieutenant-Colonel J. C.
Murphy, Captain J. F. (Special Reserve).
Nimmo, Captain W. M. (attached 1st Battalion, L. North Lancs Regiment).
O'Brien-Butler, Captain C. P. (attached 5th Lancers).
Osburn, Captain A. C.
Preston, Lieutenant R. A.
Profeit, Major C. W.
Ranken, Captain H. S. (killed) (attached 1st King's Royal Rifle Corps).
Sampson, Captain F. C.
Shields, Lieutenant H. J. S. (attached 1st Battalion Irish Guards).
Stewart, Captain H.
Ware, Captain G. W. W.
Wyler, Lieutenant E. J. (Civil Surgeon).

THE CASUALTY LIST.

The following three medical officers were serving on board H.M.S. *Hawke* when she was torpedoed on Oct. 15th and are officially assumed to have sunk with her: Staff-Surgeon George Charles Cumberland Ross, R.N., Surgeon Gustavus William Musgrave Custance, R.N., and Temporary Surgeon James Digby Watson, R.N.

Among the officers of the Royal Naval Division reported to be interned at Groningen in Holland is Temporary Surgeon B. A. Playne, R.N., who is attached to the 3rd Battalion of the 1st Naval Brigade.

The following names of officers of the Royal Army Medical Corps have appeared in casualty lists since our last issue :—

Missing: Captain A. D. Fraser. Captain W. I. Thompson, previously reported missing, is now officially reported a prisoner of war, and Captain T. B. Moriarty, previously reported missing, has now rejoined.

The name of Captain M. C. Wetherell, R.A.M.C., appears in the list of wounded British officers in Paris hospitals furnished on Oct. 16th by the British Red Cross Society.

In the casualty list from South Africa appear the names of Captain W. F. L. A. Holcroaft and Captain Dalton, of the South African Medical Corps, as wounded and taken prisoner.

GONORRHŒA AMONG THE TROOPS.

Whenever large numbers of young men are gathered together far from their homes it is not unusual that gonorrhœa and other forms of venereal disease should be present. It is therefore not surprising that in several of the newly formed camps of the recently enlisted army a number of cases of gonorrhœa should have appeared. It cannot be said that the recruits in any large quantity may have already been suffering from this disease at the time of enlistment, for each applicant for service is subjected to careful examination before he is accepted. It is impossible that the presence of such a disease as gonorrhœa should escape detection in any bulk, though a certain number whose disorder was in a latent form have been enrolled. It may be taken for granted that in most instances the disease has been acquired in the new environment and under the new conditions of life. The question of what shall be done with these recruits has been embarrassing to the authorities in some places. The new conditions and the new temptations are in great part responsible for the outbreaks of the disease where they have occurred, and often an excessive amount of gratuitous alcohol supplied by enthusiastic admirers is an important factor. It is eminently undesirable to send off to the front the men affected with gonorrhœa until the disease has been cured, for on active service the facilities for the treatment of such a disease as gonorrhœa are not great, while the disabilities of a neglected sufferer may be serious. Hospital accommodation at the front is required for the sick and wounded of the war, and all the time of the medical officers may be taken up by the injuries and wounds received in the war. There is every reason, therefore, that the sufferers should be promptly restored to health.

The methods of cure of gonorrhœa which modern science has placed in our hands are sometimes rapid. Of course, the earlier the treatment is commenced the more readily and rapidly can the disease be cured; every day of delay prolongs greatly the time during which the treatment must last, but fortunately the reasons for and opportunities of concealing an attack will not be present with the recruits. At first the gonococcus is quite superficial, and if the treatment is commenced at an early stage the inflammation will be mainly confined to the anterior part of the urethra. It is generally agreed that in early cases the irrigation of the anterior urethra with weak solutions of mild antiseptics, such as solutions of organic silver compounds, is efficacious treatment; the irrigation should, however, be done with great care, for only if the treatment is carried out correctly does the method give very good results indeed. The discharge rapidly diminishes, and in a short time practically ceases, the pain soon comes to an end, and even the microscope may show the absence of the gonococcus. The time occupied in the treatment varies greatly, but the majority of cases, if attended to early, will not become very severe or develop complications. Even so, however, convalescence may be long delayed. From one of the Territorial general hospitals we learn that the majority of a not very serious number of cases have been admitted recently, and that the treatment will on the average last six weeks before the recruit can be considered absolutely safe and sound. This implies a sad waste of time in the training of the soldier, while indicating also that the infection has been incurred since enlistment. The exact value of gonococcal vaccines is not a subject of agreement. The very high hopes at first entertained of the vaccine treatment have not been fulfilled, though to a certain extent autogenous vaccines give better results. While there is a great variance in the opinions of surgeons on the point, on the whole it may be said that vaccines are best suited for the more chronic cases, which have not responded to the ordinary treatment, and that if a vaccine is used an autogenous vaccine is the more potent.

From two sources we have received information which could leave no doubt in any mind that the evil in certain localities is a real one, though it is probably not at present so widespread as these informants would seem to suggest. Thus in one Territorial general hospital which serves the needs of 36,000 troops the surgical staff have so far not seen one case of gonorrhœa; while from another district comes the statement that although this disease was at first very prevalent among the Territorials in camp the number of cases has very greatly diminished after removal to a second site and prompt treatment with injections of permanganate. Any general action would be very difficult, for it is easy to see that the mischief must have varying fomenting causes in different centres. But it ought to be possible to prevent the actual preying upon our young soldiers by libidinous women, and the resources of law and order should be drawn upon to this end. The warnings of officers and the more special instructions of the Royal Army Medical Corps to the men have done and are doing great good, the spread of temperance has had striking effect, but the sense of the public should be roused to the necessity of protecting the men who are serving us with their lives.

We understand that a committee organised by Sir Thomas Barlow and Sir Rickman Godlee is arranging for lectures on venereal diseases at some of the large camps which are being formed, and leading members of the medical profession in various parts of the country have been asked and have consented to give similar lectures to the men. Thus the matter is evidently not being lost sight of by those in authority.

BRITISH LEARNING AND THE WAR.

A representative group of British men of learning, mostly connected with our universities, have issued a reply to the German professors and men of science who recently appended to a denunciation of Great Britain an expression of their horror of war and of their zeal "for the achievements of culture." The document concludes as follows:—

> The German professors appear to think that Germany has in this matter some considerable body of sympathisers in the universities of Great Britain. They are gravely mistaken. Never within our lifetime has this country been so united on any great political issue. We ourselves have a real and deep admiration for German scholarship and science. We have many ties with Germany—ties of comradeship, of respect, and of affection. We grieve profoundly that, under the baleful influence of a military system and its lawless dreams of conquest, she whom we once honoured now stands revealed as the common enemy of Europe and of all peoples which respect the law of nations. We must carry on the war on which we have entered. For us, as for Belgium, it is a war of defence, waged for liberty and peace.

Among the signatories the following are so well known to the medical profession that no description of their positions is required: Sir Clifford Allbutt, Sir Charles Ball, Sir Thomas Barlow, Sir Watson Cheyne, Sir James Crichton-Browne, Sir William Crookes, Sir Francis Darwin, Sir Archibald Geikie, Sir Rickman Godlee, Dr. J. S. Haldane, Sir Wilmot Herringham, Professor J. N. Langley, Sir Oliver Lodge, Sir Donald MacAlister, Sir William Macewen, Sir Patrick Manson, Dr. F. W. Mott, Professor G. H. F. Nuttall, Sir William Osler, Sir Isambard Owen, Sir William Ramsay, Sir Ronald Ross, Professor Arthur Schuster, Professor C. S. Sherrington, Sir William Turner, and Sir Almroth Wright.

THE HEALTH OF THE HOME ARMY: A REPRESENTATIVE SANITARY SERVICE.

In a speech delivered at Buckley, Flintshire, on Monday Mr. Herbert Lewis, M.P., Parliamentary Secretary of the Local Government Board, referred to the excellent condition of health of the home army, and mentioned that only ten cases of enteric fever had been notified in the week ending Oct. 10th among the 600,000 men who were then serving, a number to which substantial addition has been made. There is no reason why the freedom from disease on which Mr. Lewis commented should not be maintained, although the concentration of large bodies of young men in camps and in public buildings and billets must bring into existence conditions which are very different from those with which the civil population is associated in time of peace, and to one side of this situation we refer in a separate note.

The country is much indebted to Sir Alfred Keogh for the encouragement which he gave to the movement for utilising the services of the medical officers of health of this country in assisting to preserve the health of the troops when mobilisation took place. In London these efforts at once had effect, and very shortly after the declaration of war the whole of the billets and encampments in the London military district were under the supervision of these officers. In the same way the localities in which troops of the London district were quartered in the neighbouring counties were brought under skilled sanitary supervision through the coöperation of the county medical officers of health, who were of course in intimate relation with the medical officers of health of districts, and who were thus able to make immediate arrangements for a system of sanitary supervision to be instituted. Whatever may arise in the future with which the health officers can deal is therefore provided for, and the coördination of the military and civil services for safeguarding the health of troops at which Sir Alfred Keogh aimed has been effected without loss of time.

The Society of Medical Officers of Health has placed its organisation at the service of the military authorities. It was stated by Mr. Herbert Lewis on the occasion to which we have referred, and as was explained last week by the president of the society, Dr. Herbert Jones, in his presidential address. The medical inspectors of the Local Government Board have been engaged in efforts to coördinate the two services in such a way as to provide for the sanitary supervision of billets and encampments, and for dealing with any sanitary questions which may arise. The steps which have already been taken have therefore provided machinery required under the special circumstances to which mobilisation has given rise, but there must necessarily be a number of points arising which will require to be settled before the organisation is complete.

For this purpose it is proposed to appoint a committee consisting of members who will represent the civil sanitary service on the one hand and the military authorities on the other. The intention to appoint such a committee has been announced, and it may be expected that its constitution will shortly be made known. If the county organisation be taken as a basis and county medical officers of health be invited to assist in a scheme of administration much of the difficulty attendant upon the division of England into sanitary districts, some of which are quite small, would be obviated. The war is only in an early stage, and as yet sufficient time has not elapsed to give opportunity for epidemic disease to be introduced into this country from abroad. At any rate, if later we should find the country invaded by small-pox or cholera there will be no difficulty in coping with it, and every step will be able to be taken to preserve the home army from special risks due to their concentration in the camps which are being formed.

GOVERNMENT VACCINES FROM THE INOCULATION DEPARTMENT OF ST. MARY'S HOSPITAL.

The Inoculation Department of St. Mary's Hospital has been busily occupied since the beginning of the war in preparing doses of vaccines for the British Expeditionary Force and the Allied armies generally. The total number of doses of vaccine supplied by the end of last week was 1,476,374, which represents approximately 166 gallons of liquid. These have been prepared by the staff of the department under the supervision of Captain S. R. Douglas, I.M.S. (ret.), Captain A. F. Hayden, I.M.S. (ret.), Dr. Alexander Fleming, Dr. John Matthews, and Dr. John Freeman. The preparation of these large quantities has been much facilitated by the use of the culture medium described in THE LANCET of Oct. 10th, p. 891. In addition to antityphoid vaccine, an "antisepsis" vaccine has also been made, consisting of 500 million staphylococcus aureus and 25 million streptococcus erysipelatis in each dose of 0·5 c.c. The idea is that such a dose might usefully be given in cases in which sepsis is to be apprehended or is commencing, while a much smaller dose, 0·05 c.c., might be given when such sepsis has established itself in the form of a septicæmia. In addition to preparing this antisepsis vaccine for the British army and navy, the inoculation department has sent 200,000 doses to the French army and 100,000 doses to the Belgian army, and its latest undertaking is to send 100,000 doses to the Russian army, and more if needed. We understand that Sir Almroth Wright, whose departure for France is announced elsewhere, is accompanied by Dr. Fleming with the object of ascertaining whether these vaccines are being used to full advantage and to consider the possibility of other vaccines being supplied. Another member of the inoculation staff may go to Galicia *viâ* Russia to obtain a culture of cholera. In the meantine the remainder of the staff will endeavour to keep abreast of the demand for vaccines.

OBITUARY OF THE WAR.

HARRY SHERWOOD RANKEN, M.B., CH.B. GLASG., M.R.C.P. LOND.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain H. S. Ranken, who died at Braisne on Sept. 25th from wounds received in action on Sept. 19th, was the elder son of the Rev. Henry Ranken, B.D., minister of Irvine parish, and in the Scots phrase was thus "a son of the manse." He was born on Sept. 3rd, 1883, and was educated at the Irvine Royal Academy, at Anderson's College, and at the University of Glasgow, where he graduated in medicine, with commendation in 1905. After qualifying he held the posts of resident house surgeon and house physician at the Glasgow Western Infirmary and assistant medical officer at the Brook Fever Hospital under the Metropolitan Asylums Board. He joined the Royal Army Medical Corps in January, 1909, taking first place at the entrance examination, and retaining this place at the examination during the probationary course. He also gained the Tulloch medal, the medal for military medicine, the medal and prize for tropical medicine, the De Chaumont prize in hygiene, and the prize of £20 for grand aggregate of marks in all examinations during the probationary course, open to the Royal Army Medical Corps and the Indian Medical Service. From 1909 to 1911 Lieutenant Ranken was stationed in London under the Eastern Command, and during this period was assistant to Sir William Leishman at the Royal Army Medical College and to Dr. H. G. Plimmer in the Brown Institute, and engaged himself in research work, particularly in connexion with sleeping sickness. In 1910 he obtained the M.R.C.P. diploma, and in the following year passed the examination for captaincy with special certificate and was promoted captain in July, 1912. During these years he contributed, jointly with Major W. B. Fry and Dr. Plimmer, several important papers on trypanosomiasis, which were published in the Proceedings of the Royal Society. From August, 1911, until June, 1914, he served as a member of the Soudan Government Sleeping Sickness Commission, and was in charge of the camp at Yei in the Lado enclave. When war was declared Captain Ranken volunteered for service with the Expeditionary Force, and was attached to the 1st Battalion King's Royal Rifle Corps. For his gallant conduct in the field he was recommended for the Victoria Cross by the officer commanding, and his name is mentioned in Sir John French's despatch. The bare record of his scientific and professional career shows that he was a man of unusual ability with a special leaning towards research, and his early and heroic death robs the Royal Army Medical Corps of one of its most promising and accomplished junior officers. Captain Ranken was a keen big game shot in the Soudan, and was a "scratch" golfer, representing his University in several matches and winning many cups and other prizes.

THOMAS SCATCHARD, L.M.S.S.A.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

Captain Thomas Scatchard, who was killed in action on Sept. 8th, was born at Boston Spa on July 6th, 1878. He was the youngest son of Dr. T. E. Scatchard, whose family have been medical practitioners in that district of Yorkshire for several generations. He was educated at Epsom College and Leeds Medical School. He qualified in 1902 and entered the Royal Army Medical Corps in July, 1905, after having acted as house physician to the Leeds Infirmary and house surgeon to the Beckett Hospital, Barnsley. He spent the first 18 months of his military life at Aldershot, and then served at various stations in India for 5½ years, being promoted captain in 1909. Whilst in India he married the youngest daughter of the late Colonel de la Motte Hervey. Captain Scatchard was at the Connaught Hospital, Aldershot, before the outbreak of war, in charge of the salvarsan department, and was an examiner in this subject for promotion to the rank of captain. On mobilisation he was attached to the 26th Brigade, Royal Field Artillery, and sailed for France on August 15th. He was killed, with General Finlay and Colonel Grant Duff, by the bursting of a shell upon the Brigade Staff while on march between Choisy and Basseville. Captain Scatchard was a keen sportsman, devoted to fishing and shooting, a very good lawn-tennis player, and a great lover of animals, particularly horses.

JOHN FORBES O'CONNELL, M.B., B.S. LOND.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant J. F. O'Connell, who was killed in action on Sept. 20th during the battle of the Aisne, was the elder son of Lieutenant-Colonel D. V. O'Connell, R.A.M.C. (retired), and the great-grandson of Dr. James Forbes, Inspector-General of the Forces, who served with distinction in the Peninsular war and was the founder of the Army Medical Mess at Fort Pitt, Chatham. He was born on Feb. 18th, 1889, at Neemuch, Central India, where his father was then serving. He was educated at Epsom College, where he gained an entrance scholarship, and at St. Mary's Hospital, from which he graduated M.B., B.S. of the University of London in 1912, having obtained the Licence of the Society of Apothecaries a few months previously. After serving as house physician at St. Mary's Hospital and assistant resident medical officer at Hanwell Asylum, he joined the Royal Army Medical Corps in January, 1913, taking fifth place at the entrance examination. He was an ardent Rugby football player, and twice captained his hospital team, besides playing for the London Welsh and London Irish clubs.

Until his departure for the front on August 14th in medical charge of the 2nd Highland Light Infantry Lieutenant O'Connell was stationed at the Connaught Hospital, Aldershot. During his short life his open, generous, and cheerful nature won him many friends. Of his death, the officer commanding the Highland Light Infantry has written: "He was shot dead by a rifle bullet in the trenches while gallantly attending Second Lieutenant Fergusson who had been severely wounded. We all feel his loss most acutely. He was a general favourite with us all. He was extraordinarily brave under fire, and very hard working and popular with all ranks. The act which cost him his life was characteristic of him." Lieutenant O'Connell's early death is rendered sadder by the fact that he was married only a few months ago. His younger brother is serving with the Canadian contingent.

JAMES LAIDLAW HUGGAN, M.B., CH.B. EDIN.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

Lieutenant J. L. Huggan, who was killed at the battle of the Aisne on Sept. 16th, was born in 1890 and came of a well-known Jedburgh family. He was educated at Watson's College and at the University of Edinburgh, where he graduated M.B., Ch.B. in 1911. He was a very popular student in all circles and a general favourite, and he had an excellent record in all his professional examinations. After taking his medical degrees he acted as resident house surgeon at the Edinburgh Royal Infirmary, and then came to London to continue his studies. He joined the Royal Army Medical Corps in July, 1912, and went to the front as medical officer attached to the 3rd Battalion Coldstream Guards. Concerning his heroic death Colonel Drummond Hay has written: "Lieutenant Soames, Coldstream Guards, told me Dr. Huggan was extraordinarily gallant, and two days before he was killed he was recommended for the Victoria Cross for organising and leading a party of volunteers to remove a number of wounded from a barn that had been set on fire by the German shell fire. The work was carried out under a very heavy shell fire, and all the wounded were saved." Lieutenant Huggan's name has since been mentioned in Sir John French's latest despatch for special services in the field. As a Rugby footballer Huggan was very well known. After playing three-quarter back for Edinburgh University and the London Scottish clubs, he came very much to the front last year, and largely on account of his fine play for the Army against the Navy he was chosen to represent Scotland against England in the International match last March.

The following notes on the methods used in France for caring for the wounded are based on information obtained from the Military Service de Santé and from some of the leading Paris physicians by one of our Paris correspondents.

There was outspoken criticism of the delay which at first occurred, not only in transporting the wounded from the battlefield, but also in the trains which took them to the hospitals. Large numbers of men were left in barns lying on straw with inadequate medical attendance because the centralised authority had not foreseen the magnitude of its task and had refused to delegate its authority. All this is now being rapidly remedied.

It is still extremely difficult for any private motor ambulance, no matter how efficiently equipped, to obtain the necessary permit to go near the zone of operations, and this permit has to be renewed each week. But the problem of coping with thousands of wounded was so great that private enterprise is now allowed some play, but it must be admitted the harassed authorities were caught between the devil of the morbid curiosity mongers and the deep sea of the ubiquitous spy. Private offers were discouraged and the three branches of the French Red Cross were only allowed to receive the wounded distributed by the military authorities, but not to go and get them. Madame Michel Ephrussi has just given the army a perfectly organised sanitary train of 12 wagons and a luggage van fitted up as a kitchen and pharmacy. Dr. Tuffier, of the Hôpital Beaujon, one of the most famous Paris surgeons, who has just made a tour of inspection of the medical arrangements at the front, states that the sanitary train with complete convenience exists only in universal exhibitions; the passenger train with its three classes contains too few patients; only the freight train can convey 500 wounded, and as it is these trains which bring the supplies of ammunition and of food they are the only ones present which can be used. The criticisms of these trains are justified, but when there were 4000 wounded to evacuate every evening it was impossible, cruel as this decision might be, to employ another means of transport.

The two great difficulties beside the initial one of the lack of any adequate organisation to cope with such numbers have been the length of the field of operations extending from 150 to 200 kilometres and the imperative necessity of using the trains primarily for the movement of troops and for their commissariat. The conditions of transport are now remedied. The ordinary trains with all danger of infection are still used for the Paris hospitals, but the rest hospitals installed in the chateaux between Paris and the fighting line are now being allowed to use their own service of motor ambulances if they are lucky enough to possess them. The American hospital installed in the Lycée Pasteur has had an admirable service of motor cars from the first, and their apparent immunity from the annoyances of red tape has been the envy of other establishments. Madame Ida Rubenstein has given a number of motors to this hospital as well as bringing in wounded by motor to the ambulance which she has installed in the Hôtel Bristol. I believe the American hospital has 20 cars, and in a short time the British Red Cross is to have 200 working in France. The need for more cars is still pressing. They can, of course, only accommodate a limited number of wounded—the usual model takes four wounded lying down and two attendants, or two badly wounded and six able to sit up—but they can get down to Paris from the front in two hours, while a cattle train without doctors or nurses has before now been left on a siding, and only arrives sometimes in 20 hours. Paris is even now much better served than the provinces, where in some cases there has been lamentable overcrowding with very insufficient equipment. But all these motors serve only to supply Paris, or, at best, the chateaux hospitals in the neighbourhood. Too much stress can hardly be laid on the urgent need that exists for a similar service for some of the provinces. Everything that exists in abundance in Paris is lacking in many districts. A friend of mine reports that in a town in the Correz department 2500 wounded were brought to a tiny hospital where no provision was made for them. A report published in Paris on Oct. 5th by an eye-witness states that in one provincial hospital the surgeons were working night and day, as there were only three to every 1000 men.

In spite of all the defects of officialdom, which I can see are being remedied as rapidly as possible, the general health of the allied troops is declared to be surprisingly good, not so many cases of disease being reported as in times of peace. There have been a few isolated cases of typhoid and scarlet fever among the recruits. Rigorous precautions have been taken to prevent the spread of infection, and the mortality among the typhoid cases has only been 6 per cent. and among the scarlet fever 2 per cent.

The head surgeon in one of the big Paris ambulance hospitals gave me the following observations made in the course of his work. Alluding to dum-dum bullets, he said it is practically impossible to decide if a wound has been caused by a dum-dum or not in isolated examples. If a man is hit by a shrapnel bullet at a distance of 500 yards and the ball happens to splinter a bone instead of merely passing through tissue it makes a large hole on leaving the body exactly like a dum-dum bullet would do. Another possibility is that the bullet may be flattened and made jagged or practically turned into a dum-dum after leaving the gun by the simple fact of striking some hard substance, such as a stone, another projectile in the air, or even part of the soldier's accoutrements before it strikes him, making a dangerous wound.

An interesting fact which he noted is the rarity of abdominal wounds. Wounds in the upper and lower limbs are still the most frequent, and there have been many in the head, the spinal column, and the chest. The greater number of cases of tetanus have occurred among the German wounded. Here officialdom has been open to criticism, in the opinion of my informants. On Oct. 6th an order was issued from the French Minister of War that no serum was to be sent from the Pasteur Institute without an order from Bordeaux. Luckily most of the hospitals had already laid in a stock, but in case this gives out a patient might die ten times over before an order for the serum could possibly be sent for and return from Bordeaux in the present state of the post. It is realised in Paris that the serum should be given to every wounded soldier as soon as he is taken off the battlefield; if there is a delay till he finally gets to hospital the disease is often too far advanced for hope. The military authorities possess two-thirds of the stock of serum available. The reason for the order was the danger of the stock giving out if used indiscriminately. Inquiries made at the Pasteur Institute prove that there is little fear of any shortage in the supply. It is now possible to furnish 4000 bottles of serum per day, and in three months' time a further supply can be guaranteed.

THE WOUNDED IN THE WAR.

We publish this week a review by Mr. G. H. Makins, consulting surgeon to the Forces Oversea, upon the wounded in the present campaign, which shows clearly the great improvement that has taken place in the condition of the patients under the more satisfactory arrangements for transport that are now possible, and which day by day are leading to the disappearance of the methods graphically portrayed below by a Paris correspondent. The abatement of tetanus is most satisfactory, while the efforts at treatment have been assiduous. Mr. Edmund Owen's notes on the cases of wounded that came suddenly under his care, and that of the staff at the Epsom and Ewell War Hospital, indicate the terrible severity of many of the shell wounds, and his testimony to the courage of the sufferers is moving. The report by Staff Surgeon Pick, Surgeon Rankine, and Surgeon Lambert of the cases which came under their care after engagements in the North Sea also illustrates the severity of the shell wounds received and the value of good first aid. In many of the cases the interval between the infliction of the injury and the commencement of anything more than first-aid treatment amounted to many hours, so that often the degree of shock was very great, but it is clear that the first aid that was afforded did much to check septic processes. The features of the wounds caused by the shells were in many respects remarkable. In some the shell fragment had scooped out a portion of tissue, so that there was no wound of entrance or exit, but merely a complete loss of the superficial tissues. In punctured wounds the fragment sometimes buried itself deeply, while in others it made a long subcutaneous track. Whenever serge from the clothing was carried in with the shell fragment the wound was more septic than when pieces of linen were present; this is a little difficult to explain. The German sailors were wearing lifebelts when in action, so that in many cases pieces of cork from the belts were found in the wounds. The paper is one of the earliest to report the injuries produced by high explosives, and attention may also be drawn to the testimony of the authors to the value of vaccines.

WORK OF THE BRITISH RED CROSS SOCIETY.—In a summary of the work accomplished during the week ending Oct. 21st the British Red Cross Society states that the total number of beds in the auxiliary home hospitals approved by the War Office is now 6480, and between 50 and 60 Voluntary Aid Detachments are being utilised in connexion with these hospitals. The amount of stores sent abroad by the Stores and Transport Department during the past week was comparatively small. This was due to the large quantity despatched in the previous week, to the desirability of keeping a full stock of supplies in view of the great influx of Belgians into England, and to the change of headquarters in France from Paris to Bolougne. In response to a sudden call from the War Office hospital clothing for 1000 Indian soldiers was sent to Netley the same evening. Garments to the number of 53,787 were issued during the week, and £2235 were expended upon purely medical stores. The society now has six surgeons always at hand ready to be sent in response to emergency calls, while the personnel of the ambulance train is being got ready, and a permanent "emergency unit" of 12 nurses is now ready. During the week 37 motor ambulances and 2 motor cycles were despatched to the Continent, and 13 ambulances were furnished to the War Office. The Army Council has expressed its appreciation of the assistance rendered by the Voluntary Aid Detachments in the Eastern Command during the disembarkation and disposal of the sick and wounded Belgian soldiers arriving between Oct. 12th and 16th.

WOUNDED AT LONDON HOSPITALS.—328 Belgian wounded have been received at the London Hospital, Whitechapel-road. They have been through the siege of Antwerp and were brought to England when that city was evacuated. All the English wounded who were originally taken in at this hospital have been discharged. 50 wounded Belgian soldiers have been received in St. Bartholomew's Hospital, and 11 wounded Belgian officers at the Red Cross Hospital in Fishmongers' Hall. Most of the wounds have been due to shrapnel.

EDINBURGH IN WAR TIME.—Our Edinburgh correspondent writes: Lord Kitchener's nomination as Rector of the University has been welcomed by all sections of the undergraduates, and as there will be no contest the nomination and election will take place together on Oct. 24th. The winter session of the University opened on Oct. 6th. From the matriculation figures it appears that there is a fall in the number of students of fully 400, due to the fact that so many men have replied to the call of the country. 230 members of the Officers' Training Corps have received commissions: Artillery, 111; infantry, 78; engineers, 10; medical, 31; while over 60 of the last unit form the field ambulance section of the Scottish Horse. About 100 are Territorials and distributed between the Edinburgh new battalion, the Scottish Horse, and many other corps. When all are summed up the total number of students and graduates should be 1000. What will rank as one of the quietest graduation ceremonies held in connexion with this University took place in the McEwan Hall on Oct. 16th. There was an entire absence of the usual display of student spirits, and the attendance both of students and of the public was smaller than usual. For these features the shadow of the war is accountable. Principal Sir William Turner, who has completed 60 years of service for the University—demonstrator in and then professor of anatomy, and finally principal and vice-chancellor—occupied the chair.

Dalmeny House, which the Earl of Rosebery has generously placed at the disposal of the naval and military authorities for the treatment of wounded, was called into service for the first time on Oct. 16th, when a trainload of sick and wounded from the battle front in France arrived in Edinburgh and were conveyed by motor transport to the hospital. Men from a number of regiments were among the detachment, and the Red Cross Society rendered valuable assistance by having a fleet of over 30 motor vehicles in readiness at the station for the conveyance of these patients.—On the night of Oct. 17th an ambulance train from Southampton arrived at Prince's-street Station. The wounded men numbered about 100. All were taken to the Royal Infirmary. The majority of the men were wounded round Béthune and Lille.—On Monday morning, Oct. 19th, at the early hour of 5 o'clock, another body of wounded numbering about 100 arrived at Prince's-street and were conveyed in motor ambulances and private cars to Craigleith Hospital.

AUSTRALIA AND THE WAR.—Our Australian correspondent sends the following timely details:—"The war is the sole topic of interest, and preparations are going forward actively for the despatch of Australian contingents. The volunteering has been satisfactory, and the medical officers have been somewhat strict in their examination, so that physically the Commonwealth force will be a fine fighting unit. It is now announced that in addition to the field medical equipment with the troops the Minister of Defence proposes to send a light horse field ambulance, a field ambulance, a clearing hospital, two stationary hospitals, and two general hospitals. These will require about 1000 persons of all ranks, including trained nurses and 80 medical officers. Many well-known medical men have volunteered. An interesting feature of the medical outfit already in the field is an X ray plant mounted upon a motor-car and freely movable at top speed. It has been designed and carried out by Dr. Stanley Argyle, specialist to the Alfred Hospital and its cost was borne by private subscription. It will be in charge of Captain Nicholas, late resident at the Melbourne Hospital. The *Grantala* has been fitted as a hospital ship with a staff of seven or eight surgeons and Mr. W. James, M.S. Melb., as consulting surgeon, and is in commission. Amongst civil surgeons who have offered their services and been accepted is Mr. F. D. Bird, lecturer in surgery at the Melbourne University, and he will provide two nurses for hospital duty. Vaccine for the preventive inoculation of enteric fever has been prepared by the New South Wales Department of Public Health and will be available for the medical profession. It will also be used for inoculation among the troops being despatched to the war. Sufficient to treat 22,000 men is said to have been supplied at a cost of about 1*d.* per man."

THE QUEEN'S CANADIAN MILITARY HOSPITAL.—With the approval of the War Office, Beachborough Park, near Shorncliffe, has been placed by Sir Arthur and Lady Markham at the disposal of the Canadian War Contingent Association for use as a military hospital, and for this purpose it has now been prepared and equipped. It is to be known as the Queen's Canadian Military Hospital and has accommodation for upwards of 50 patients. The medical and surgical organisation is under the supervision respectively of Sir William Osler and Mr. Donald Armour. The nursing staff consists of Canadian-trained nurses under the superintendence of Miss Amy MacMahon, of Toronto.

LONDON PANEL PRACTITIONERS' GIFT.—The motor ambulance presented by the practitioners on the panel in the County of London has been handed over to the British Red Cross Society and will immediately be sent to France for use in bringing wounded soldiers from the front to the base hospitals.

BELGIAN WOUNDED AT HASLAR.—The first large batch of wounded and sick to be admitted to the Royal Naval Hospital, Haslar, for treatment since the outbreak of the war arrived on Oct. 13th. They numbered 572, all Belgians, including 142 officers. They were chiefly victims of the bombardment of Antwerp. Some were seriously injured, but a few were refugees, who have now been sent elsewhere.

Dr. John Cosmo Stuart Rashleigh, of Throwleigh, Okehampton, has presented a fully equipped motor ambulance to the British Red Cross Society, and is himself going to the front with the ambulance.

MEDICAL MAGISTRATE.—Dr. Edmund Hobhouse has been placed on the commission of the peace for the borough of Hove.

Medical News.

UNIVERSITY OF OXFORD.—The following medical degrees have been conferred:—

D.M.—H. J. B. Fry, Magdalen; and O. A. R. Berkeley-Hill, Trinity (*in absentiá*).

UNIVERSITY OF CAMBRIDGE.—The following medical degrees have been conferred:—

M.D.—R. F. Higgin, Caius.

M.B., B.C.—C. G. H. Moore, Caius; and L. E. S. Sharpe, Trinity.

The following candidates have satisfied the examiners in both parts of the examination in Sanitary Science:—

Edward Bach, James Lionel Bocarro, Jane Malcolm Davidson, Leander Lowrie Fyfe, Hirji Dorabji Gimi, Ignatius James Khaw Oo Kek, John McCallum Lang, Ram Chandr Malhotra, Bidham Prosad Mozoomdar, *William Henry Peacock, Raghu Nath Roy, and †Ashley George Gyton Thompson.

* Distinguished in the practical application of sanitary science and pathology. † Distinguished in bacteriology.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—At the examinations conducted on Oct. 7th for the Licence in Dental Surgery, the following Associates passed the Final Examination and were admitted Licentiates in Dental Surgery:—

Roland Harry Bebb, Walsall; Francis Edward Stuart Brailsford, Enfield, Middlesex; John Stewart Marshall Connell, Glasgow; John Graham, Stirling; William Gilmour Gray, Glengarnock; Arthur William Whewell Holmes, Hest Bank, Lancaster; Percy Hope Johnstone, Leytonstone, Essex; James Alexander M'Gowan, Elgin; and Frederick William Robinson, Erdington, Birmingham.

SOCIETY OF APOTHECARIES OF LONDON.—Mr. Meredith Townsend, M.R.C.S. Eng., has been elected Master of the Society of Apothecaries for the ensuing year, and the new wardens are Dr. George Amsden and Mr. A. H. W. Ayling.

ROYAL SANITARY INSTITUTE.—The following medical practitioners have this month been elected members of the Royal Sanitary Institute:—Dr. J. D. Buchanan (Lancaster), Dr. W. A. Daley (Bootle), Dr. G. H. Dart (Greenwich), Dr. F. Hauxwell and Dr. S. J. E. Holden (St. Helens), Mr. W. M. McIlraith (Rawtenstall), Mr. C. D. Outred (Gravesend), and Dr. A. E. Townley (Oswaldthistle).

THE next meeting of the Life Assurance Medical Officers' Association will be held at 1, Wimpole-street, W., in the rooms of the Royal Society of Medicine on Wednesday, Nov. 4th, at 5.30 P.M., when Dr. H. J. Cardale and Dr. J. Fletcher Porter will initiate a discussion on "The Certification of Invalidity under the National Insurance Act." The association will welcome the presence of any medical man.

CHARING CROSS HOSPITAL: THE HUXLEY LECTURE.—The Huxley Memorial Lecture on Recent Advances in Science in Relation to Medicine and Surgery will be delivered in the hospital on Monday, Nov. 2nd, at 3 P.M., by Sir Ronald Ross, F.R.S., Sir Thomas Barlow, Bart., President of the Royal College of Physicians of London, in the chair. The lecture is open to all members of the medical profession.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At the annual general meeting of this society, held on Oct. 16th at 1, Upper Montague-street, London, W.C., Dr. Herbert Jones, D.P.H., was inducted as President for the ensuing year and delivered his presidential address upon "The Public Health Service and the National Crisis." Sir Arthur Whitelegge and Dr. Edward C. Seaton were elected honorary Fellows, and Dr. E. W. Hope was presented with his portrait by the North-Western Branch of the society.

HUNTERIAN SOCIETY.—The Presidential address will be delivered by Dr. T. Glover Lyon at the Barbers' Hall, Monkwell-street, E.C., on Wednesday next, Oct. 28th, at 4.30 P.M. Dr. Glover Lyon will take for his subject "The Barber-Surgeons and the Medical Profession." The address will be illustrated by many objects of interest belonging to the company, including the famous painting by Holbein of the granting of a charter to the company, the cup presented by Henry VIII., and another cup presented by Charles II.

These and other numerous works of art and relics will be displayed for the inspection of Fellows and visitors. Sir Thomas B. Crosby, M.D., hopes to be present and to address the meeting on the relation of the Barbers' Company to the corporate life of the City of London. Tea will be served at 4 P.M. All members of the medical profession are cordially invited.

Royal College of Physicians of Ireland.—The annual meeting of the Royal College of Physicians of Ireland was held on the morrow of St. Luke's day. The annual dinner was pretermitted on account of the war. Dr. C. E. FitzGerald's term of office as president has concluded, to the great regret of the Fellows. He attended to his duties with great assiduity, and by his courtesy to all, and by his ready grasp of matters under discussion, he guided the College business with success. He is succeeded by Dr. E. MacD. Cosgrave.

The Child-Study Society, London.—The following programme of lectures has been arranged for the present session: Oct. 29th, Miss Evelyn Fox, on the After-care of Mental Defectives; Nov. 5th, Mr. P. Macleod Yearsley, F.R.C.S., on the Classification of the Deaf Child for Educational Purposes; Nov. 19th, Dr. T. Percy Nunn, on Development of the Practical Imagination in Children; Dec. 3rd, Miss Margaret Corner, M.A., on Self-expression through Language with Older Children. The meetings will be held at 7.30 P.M. at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Boreham, H. W., M.B., B.Ch. Edin., has been appointed Clinical Tutor in the Edinburgh Royal Infirmary.

Coates, W. Harrison, M.R.C.S., L.S.A., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Hucknall Torkard District of the county of Nottingham.

Dickie, J. K. Milne, M.D. Edin., has been appointed Clinical Tutor in the Edinburgh Royal Infirmary.

Graham, G. M., F.R.C.S. Edin., has been appointed Surgeon to the Craigleith Hospital.

Johnstone, G. Gordon, M.B., B.C. Cantab., has been appointed Clinical Assistant in the Ophthalmic Department at University College Hospital.

Johnstone, R. W., M.D. Edin., has been appointed Clinical Tutor in the Edinburgh Royal Infirmary.

Jones, G. J., M.B., B.S. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Rathfriland District of the county of Down.

Madill, J. H., M.B., Ch.B. Edin., has been appointed Clinical Assistant in the Edinburgh Royal Infirmary.

Martin, E. K., M.B. Lond., F.R.C.S. Eng., has been appointed Junior Surgical Registrar at University College Hospital.

Mathewson, George D., M.B. Edin., has been appointed Clinical Assistant in the Edinburgh Royal Infirmary.

Ritchie, A. G., M.B., Ch.B. Edin., has been appointed Clinical Tutor in the Edinburgh Royal Infirmary.

Rutherford, Andrew, M.B., Ch.B. Edin., has been appointed Clinical Tutor in the Edinburgh Royal Infirmary.

Steele-Perkins, Duncombe Steele, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer in charge of Troops at Honiton, Devon.

Stephen, J. W., M.B., Ch.B. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Beith District of the county of Ayr.

Taylor, Mark Ronald, L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for the Wendron District by the Helston (Cornwall) Board of Guardians.

Thompson, Robert Busher, M.B., Ch.B. Vict., has been appointed Medical Officer for Brixham and Churston District by the Totnes (Devon) Board of Guardians.

Thomson, H. J., M.B., Ch.B. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Alford District of the county of Aberdeen.

Young, James, M.D. Edin., has been appointed Clinical Tutor in the Edinburgh Royal Infirmary.

Yule, Robert Mortimer, M.D. Aberd., has been appointed a Medical Referee under the Workmen's Compensation Act, 1906, for the Sheriffdom of Caithness, Orkney, and Shetland, to be attached more particularly to the Shetland District.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Ayr District Asylum.—Assistant Physician. Salary £200 per annum, with board, apartments, laundry, and attendance.

Birkenhead Borough Hospital.—Junior House Surgeon. Salary £100 per annum, with board and laundry.

Birmingham City Asylum, Rubery-hill.—Junior Assistant Medical Officer. Salary £200 per annum, with apartments, board, laundry, &c.

Birmingham Union.—Dudley-road Infirmary: Third Assistant Medical Officer and Fourth Assistant Medical Officer. Salary at rate of £170 and £160 per annum respectively. Erdington Infirmary and Cottage Homes: Assistant Medical Officer. Salary at rate of £200 per annum. Selly Oak Infirmary: Assistant Medical Officer. Salary at rate of £180 per annum. Apartments, rations, laundry, and attendance in each case.

Bootle, Corporation Hospital for Infectious Diseases.—Resident Medical Officer, unmarried. Salary £250 per annum, with board, washing, and apartments.

Bristol City Asylum, Fishponds.—Second Assistant Medical Officer, unmarried. Salary £250 per annum, with apartments, board, washing, and attendance.

Bromsgrove, Worcestershire Asylum.—Deputy Medical Superintendent and Second Assistant Medical Officer. Salary £300 and £225 per annum respectively, with apartments, board, washing, and attendance.

Burslem, Haywood Hospital.—Female Resident Medical Officer. Salary £100 per annum, with board, residence, and laundry.

Bury and District Joint Hospital Board.—Assistant to Medical Superintendent. Salary £200 per annum, with board, washing, and lodging.

Canterbury, Kent County Asylum, Chartham.—Junior Assistant Third Medical Officer, unmarried. Salary £250 per annum, with quarters, board, washing, &c.

Chelsea Hospital for Women, Fulham-road, S.W.—Dental Surgeon.

Cheshire Education Committee.—Fourth Assistant to the Chief School Medical Officer. Salary £350 per annum.

Chesterfield and North Derbyshire Hospital.—Senior House Surgeon. Salary £200 per annum, with board, apartments, and laundry.

Chichester, Royal West Sussex Hospital.—House Surgeon, unmarried. Salary £110 per annum, with board, residence, and washing.

City of Westminster Union Infirmary, Fulham-road, S.W.—Second Assistant Medical Officer and Third Assistant Medical Officer. Salaries £160 and £140 per annum respectively, with board, residence, and washing.

Constance-road Institution, Grove Vale, East Dulwich.—Temporary Resident Medical Officer. Salary at rate of £225 per annum, with apartments, board, washing, &c.

Derby County Sanatorium.—Resident Assistant. Salary £250 per annum, with board, lodging, and laundry.

Douglas, Noble's Isle of Man Hospital.—Resident House Surgeon, unmarried. Salary £150 per annum, with board and washing.

Durham County Council.—Female Assistant School Medical Officer. Salary £300 per annum.

Evelina Hospital for Sick Children, Southwark, S.E.—House Physician for six months. Also House Surgeon for four months. Salary at rate of £75 per annum, with board, residence, and washing.

Exeter City Asylum.—Medical Superintendent. Salary £500 per annum, with unfurnished house, coal, lighting, laundry, &c.

Gateshead Asylum, Stannington, Northumberland.—Assistant Medical Officer, unmarried. Salary £220 per annum, with rooms, board, and laundry.

Glamorgan County Council.—Medical Officer. Salary £250 per annum.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, residence, and washing.

Great Yarmouth County Borough.—Assistant Medical Officer of Health. Salary £250 per annum.

Great Yarmouth Hospital.—House Surgeon, unmarried. Salary £140 per annum, with board, lodging, and washing.

Greenwich, Dreadnought Hospital.—House Surgeon and Casualty Officer. Salary at rate of £50 per annum each, with board, residence, and washing.

Halifax Royal Infirmary.—Second and Third House Surgeons, both unmarried. Salaries £120 and £100 per annum respectively, with residence, board, and washing.

Harrogate Infirmary.—Resident House Surgeon. Salary £100 per annum.

Harrow-on-the-Hill Urban District Council.—Medical Officer of Health. Salary at rate of £200 per annum.

Hereford County and City Asylum.—Junior Assistant Medical Officer. Salary £200 per annum and all found except stimulants.

Huddersfield Royal Infirmary.—Senior and Junior Assistant House Surgeons. Salary £80 per annum each, with board, rooms, and washing.

Hull Royal Infirmary.—Senior House Surgeon, unmarried. Salary £150 per annum, with board and apartments. Also Assistant House Surgeon. Salary at rate of £100 per annum, with board and lodging. Also Honorary Assistant Medical Officer to attend Out-patients' Department.

King's Lynn, Lynn and West Norfolk Hospital.—House Surgeon. Salary £150 per annum.

Leeds, Hospital for Women and Children.—Two House Surgeons for six months. Salary at rate of £50 per annum, with board.

Leicester Royal Infirmary.—Resident Assistant House Surgeons and Dressers.

Liverpool, St. Paul's Eye Hospital.—House Surgeon. Salary £80 per annum, with board and residence.

Manchester, Ancoats Hospital, Mill-street.—Assistant House Surgeon. Salary £70 per annum, with board and residence.

Manchester, County Asylum, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

Manchester, Hulme Dispensary, Dale-street, Stretford-road.—House Surgeon. Salary £180 per annum, with apartments, attendance, coal, and gas.

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

Manchester Poor-law Institution, Crumpsall.—Second Resident Assistant Medical Officer and Junior Resident Assistant Medical Officer, both unmarried. Salary £180 and £160 per annum respectively, with rations, apartments, fire, light, washing, and attendance.

Manchester Royal Eye Hospital.—Junior House Surgeon. Salary £80 per annum, with residence, board, and washing.

Metropolitan Asylums Board Infectious Hospitals Service.—Assistant Medical Officers, unmarried. Salary £250 per annum, with board, lodging, and washing.

Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W.—House Surgeon. Salary £150 per annum.

Middlesbrough, North Ormesby Hospital.—House Surgeon. Salary £120 per annum, with board, washing, and attendance.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Junior House Surgeon for six months. Salary £85 per annum, with board, residence, and laundry.

Mount Vernon Hospital for Consumption and Diseases of the Chest.—Assistant Physician.

Newcastle-upon-Tyne and Northumberland Sanatorium for Consumptives, Barrasford, North Tyne.—Resident Medical Officer, unmarried. Salary £350 per annum, with board, residence, and laundry.

Newcastle-upon-Tyne Hospital for Sick Children.—Senior Medical Officer and Junior Medical Officer for six months. Salary £100 and £80 per annum respectively, with board, lodging, and laundry.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Four House Physicians, Four House Surgeons, Accident Room House Surgeon. House Surgeon to the Aural and Ophthalmic Department, House Surgeon to the Skin and Gynæcological Department, and House Surgeon to the Out-patient Dressing Department.

Newport (Mon.), Royal Gwent Hospital.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

Northampton County Asylum, Berry Wood.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

Northampton General Hospital.—Two House Surgeons. Salary £120 per annum, with apartments, board, washing, attendance, &c.

Nottingham Children's Hospital.—Female House Surgeon for six months. Salary at rate of £130 per annum, with apartments, board, and washing.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Ballinamore, in the county of Leitrim; and at Woburn Sands, in the county of Bedford.

Births, Marriages, and Deaths.

BIRTHS.

Ackroyd.—On Oct. 20th, at Royston, Herts, the wife of Harold Ackroyd, M.D., of a son.

Brown.—On Oct. 19th, at Kensington Park-road, W., to Dr. and Mrs. David Brown, of Tientsin, China, a son.

Caddy.—On Oct. 13th, at Richmond, Surrey, the wife of Dr. Adrian Caddy, F.R.C.S., of Calcutta, of a daughter.

Dally.—On Oct. 20th, at 19, Upper Wimpole-street, W., the wife of J. F. Halls Dally, M.A., M.D., M.R.C.P., of a daughter.

Fennell.—On Oct. 17th, at the Manor House, West Hoathly, the wife of Charles Henry Fennell, M.D., of a daughter.

Good.—On Oct. 13th, at High Bickington, N. Devon, the wife of Arnold Saxty Good, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

MacNabb—Bywater.—On Oct. 17th, at St. Cuthbert's Church, Edinburgh, H. H. MacNabb, M.D., of Manchester, to Annie Emily, second daughter of Mrs. Bywater, of Innescote, Roxburgh.

Russell—Lambert.—On Oct. 15th, at St. Peter's Church, Woodmansterne, Surrey, Trevor Cecil Russell, Prob. Surg. R.N.V.R., to Joyce Ethel Julia, second daughter of Colonel and Mrs. Heygate Lambert, of Woodmansterne.

Smith—Hamilton.—On Oct. 17th, at St. Mary Magdalen's, Mortlake, Hector Smith, M.B., B.S. Lond., R.A.M.C. (Special Reserve), to Ada Maud Hamilton, youngest daughter of Dr. Hamilton, Essex House, Barnes, Surrey.

DEATHS.

Haldane.—On Oct. 18th, at Viewforth, Bridge of Allan, William Haldane, M.D., F.R.C.P. Edin., F.F.P.S. Glasg., aged 67 years.

Hartley.—On Oct. 3rd, at 26 Stanhope-road, Darlington, John Hartley, F.R.C.S. Eng., aged 63 years. For five years Senior Demonstrator of Anatomy at the Middlesex Hospital, London.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

During the continuance of the war the size of THE LANCET *will be curtailed. This has been necessitated primarily by the difficulty in ensuring an adequate supply of paper, but the contributions of most of our correspondents on the continent have failed, and will fail, to reach us. Many special features of* THE LANCET *have had to be sacrificed for the time, and while we ask the indulgence of our readers for this, we promise to restore them at the earliest possible opportunity.*

THE RUSSIAN GOVERNMENT AND ALCOHOL.

IT is reported that the Tsar has decided to prohibit for ever in Russia the Government sale of alcohol, while since the beginning of the war all Russian vodka shops have been closed, in the interests of public health and morality. In the sixteenth century the spirit trade was a State monopoly, but in times of urgent need of money it was found desirable to let the drinking-shops and distilleries to private persons for a certain rental. Changes from one system to another were frequent. By a ukase of August 22nd, 1794, the "otkoop" system (i.e., the letting to private persons) was introduced, but was replaced by the monopoly system by the ukase of April 2nd, 1819. In the "forties" the "otkoop" was again in force, and the last "otkoop" period was 1859-63. Then an excise system was proposed and accepted. The edict of June 6th, 1894, was issued by Russia to gain control over the trade, and the compulsory sale of spirit to the Crown at a stipulated price was enforced, which resulted in a large production, and stability of trade, and the export rebate was also reformed. In the next ten years there was a rapid development of the technical side of the trade, and the Crown demanded that only spirit of high quality and purity should be used for the manufacture of liquor, and this caused the introduction of improved apparatus.

PAIN IN THE HEEL.

To the Editor of THE LANCET.

SIR,—In reply to Dr. J. L. Martin's request for suggestions for treatment in to-day's LANCET, I have to say that pain in the heel is often associated with uric acid in excess. I have notes of three such cases in which all pain disappeared after voiding a small uric acid calculus by the urethra. I believe the late Sir James Paget drew attention to these associated conditions. I am, Sir, yours faithfully,

London, Oct. 17th, 1914. SEYMOUR TAYLOR.

To the Editor of THE LANCET.

SIR,—Replying to Dr. J. L. Martin's inquiry *re* painful heel, I find the following notes in my A B C book, taken from an article in the *Clinical Journal*, April, 1913, by Mr. A. H. Tubby:—

"*Painful Heel.*—(1) A small bony spur discoverable by X ray examination; (2) shortening of one leg (common); (3) epiphysitis of the os calcis; (4) constant standing (another common cause); (5) trauma; (6) flatfoot; (7) rheumatism, gout, syphilis, tubercle."

I may say that in a case of an old lady which baffled me for some weeks the first cause was found.

I am, Sir, yours faithfully,
CHAS. W. BUDDEN, M.D. Liverp.
Hoylake, Cheshire, Oct. 19th, 1914.

HEALTH AND SANITATION OF THE GOLD COAST.

ACCORDING to the annual Blue-book, recently forwarded to the Colonial Office by the Acting Governor (Mr. W. C. F. Robertson), the population of the Gold Coast Colony and its dependencies amounted at the last Census to 1,503,386. The number of Europeans resident in the Colony, Ashanti, and the Northern Territories is given as 2590, as compared with 2367 in 1912. Among the European population a decrease per 1000 of 3·33 in the death-rate and an increase of 1·56 in the invaliding rate are recorded. Death in the case of 6 European officials was due in 2 instances to yellow fever, in 2 to blackwater fever, in 1 to hyperpyrexia, and in 1 to meningitis. There were 11 cases of yellow fever amongst Europeans, 6 of which proved fatal. Of 30 officials invalided, 4 were for malaria, 1 for blackwater fever, 1 for neurasthenia, 2 for yellow fever, 4 for dysentery, and 18 for various other diseases. Of 82 European non-officials invalided 19 were for malaria, 13 for blackwater fever, 7 for dysentery, 5 for anæmia, 2 for gastritis, and 36 for various other diseases. The total number of Europeans coming under treatment was 1179, as compared with 1004 in 1912. No means exist whereby accurate statistics relating to the health of natives can be obtained. The returns show, however, that the number of attendances for hospital and dispensary treatment was 26,661, or 697 more than in the previous year. Treatment was given for 2565 cases of malaria, 2552 of parasitic diseases, and 853 of dysentery. In all, 49,491 cases were treated during 1913, of which 264 proved fatal, the figures for 1912 being 46,234 and 257 respectively. With the exception of an outbreak of small-pox in the eastern province of the colony, in which 108 cases were treated (18 terminating fatally), the Gold Coast and its dependencies were free from any serious outbreak of epidemic disease during the year. 61 cases of sleeping sickness were reported during the year, 15 of which terminated fatally. A new hospital for Europeans is now under construction at Accra. The sanitary conditions of the Colony, Ashanti, and the Northern Territories show generally an improvement, especially in the more populous centres. In addition to other works, 12,861,215 square yards of vegetation were cleared during the year; 607 pools or excavations were filled; 265,701 square yards of marsh land were filled and drained, and 4771 drains and 16,289 pools were treated with crude petroleum. A sum of £3204 was spent during the year on sleeping sickness preventive measures and £1552 on yellow fever preventive measures. The climate, though hot and damp, is cooler than that of most tropical countries situated in similar latitudes. The Gold Coast, owing to the prevalence in the past of mosquito-borne diseases, has gained for itself an evil reputation, but the steady progress being made in tropical medicine and hygiene and the great amount of useful work carried out on the spot by the medical and sanitary authorities are gradually redeeming its character.

THE WISCONSIN STATE MARRIAGE LAW.

ON Jan. 1st, 1914, a law passed by the State of Wisconsin the preceding year, and requiring examination by the application of the recognised clinical and laboratory tests for freedom from acquired venereal disease in the case of all male applicants for a marriage licence, came into force. On June 17th judgment was given in a test case as to its validity. The principal point on which discussion turned was whether the wording of the Act called for the application of the Wassermann test, because, if so, few medical men had the required equipment or skill, and the statutory fee of $3 was inadequate. The court held (three to two) that the law did not require this test, but only such physical examination and tests for venereal disease as were within the competence of the ordinary general practitioner and his equipment.

A VERY useful statement of the causes of the war and of what it means to Great Britain is given in a little pamphlet entitled "One Clear Call," by Henry Allen Ashton, published at the price of 1*d.* by the Voluntary Publishing Association, Empire House, Piccadilly. It is intended to stimulate recruiting by showing the vital nature of the issues at stake and the imperative need for the services of every available man. The profits, if any, of the sale are to be devoted to the furtherance of recruiting.

Messrs. Pearson's Antiseptic Co., Limited, of Elm-street, London, W.C., announce that soon after the war commenced they were asked by the Admiralty to tender for supplies of a disinfectant fluid of a similar character to German-made Lysol. They submitted a sample of their Pacolol fluid, which has been adopted by the Admiralty for use in His Majesty's medical establishments.

Messrs. Hommel's Hæmatogen, of 36, St. Andrew's-hill, Doctors' Commons, E.C., contradict a statement which has been made that they are a German firm. Their Hæmatogen is made in Switzerland by Swiss proprietors, and a continuous supply is reaching this country.

Jeyes' Sanitary Compounds Co., Limited, of 64, Cannon-street, London, E.C., the manufacturers of the soluble fluid Jeysol, wish to make it known that they are an absolutely British firm and hold Government contracts.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

FRIDAY.

OCCASIONAL LECTURE, TO FELLOWS: at 5 P.M.

In the Robert Barnes Hall.

Professor J. C. Bose, C.S.I., C.I.E., D.Sc. (Calcutta University), will give a demonstration on the Modification of Response in Plants under the Action of Drugs.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on the Operative Treatment of Tumours of the Cæcum and Colon—especially in Relation to Immediate Resection, Colostomy combined with Secondary Resection, and Short Circuiting (introduced by Mr. H. J. Waring, Mr. J. Sherren, and Mr. E. M. Corner). Exhibition of Specimens.

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

WEDNESDAY.—4.30 P.M., Presidential Address:—Dr. T. G. Lyon: The Barber-Surgeons and the Medical Profession. (Illustrated by an exhibition of objects of interest belonging to the Worshipful Company of Barbers.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Museum Demonstrations for Advanced Students and Medical Practitioners:—

MONDAY.—5 P.M., Mr. S. G. Shattock: Specimens illustrating Tuberculosis.

WEDNESDAY.—5.30 P.M., Mr. J. F. Colyer: Specimens of Dento-alveolar Abscess and Dental Cyst.

FRIDAY.—5 P.M., Prof. A. Keith: Gunshot Injuries of the Thorax and Abdomen.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Eye Department.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 10.30 A.M., Dr. Simson: Gynæcological Demonstration. 12 noon, Lecture:—Dr. G. Stewart: Neurological Cases. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12 noon, Lecture:—Dr. Bernstein: Applied Pathology. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics X Rays. Mr. Pardoe: Operations.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Lecture:—Dr. J. Taylor: Clinical Cases.

FRIDAY.—3.30 P.M., Lecture:—Dr. J. Taylor: Clinical Cases.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. K. Sibley: Alopecia.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Lichen and Lichenification.

MANCHESTER HOSPITALS POST-GRADUATE CLINICS.

THURSDAY.—ANCOATS HOSPITAL, Mill street.—4.30 P.M., Dr. C. E. Lea: Myasthenia Gravis.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

MONDAY.—10 A.M., Obstetrical Lecture: Abnormal Presentations. 11 A.M., Examination of Patients and Minor Operations.

TUESDAY.—10 A.M., Major Operations.

WEDNESDAY.—10 A.M., Obstetrical Lecture: Abnormal Presentations (continued). 11 A.M., Examination of Patients and Minor Operations.

THURSDAY.—10 A.M., Major Operations.

FRIDAY.—10 A.M., Gynæcological Lecture: Anatomy of the Uterus. 11 A.M., Examination of Patients and Minor Operations.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 [illegible]	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Harveian Oration

ON

ADVANCES IN KNOWLEDGE REGARDING THE CIRCULATION AND ATTRIBUTES OF THE BLOOD SINCE HARVEY'S TIME.

"For the Life of all Flesh is the Blood Thereof."

Delivered before the Royal College of Physicians of London on Oct. 19th, 1914.

By Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., M.D., F.R.C.P., LL.D.,

PHYSICIAN IN ORDINARY TO THE KING; CONSULTING PHYSICIAN TO THE MIDDLESEX HOSPITAL AND THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, ETC.

(Concluded from p. 984.)

Attributes of the Blood.

Harvey's life work was the demonstration of the circulation of the blood. He could speak and speculate only generally as to the composition of the blood itself. He recognises the blood as the medium in which "the life" dwells, as "the generative part, the foundation of life, the first to live, the last to die, and the primary seat of the soul" (or vital principle). He goes beyond Aristotle, whom he quotes as saying that "the blood is that alone which lives and is possessed of heat whilst life continues," and lays emphasis upon the fact that it "is the prime part that is engendered and the heart the mere organ destined for its circulation." He holds it also as primary to the vessels which are constructed to contain it. Harvey's views were thus, as we should expect, thoroughly sound so far as they could go, and, as we may see, he makes some shrewd speculations and divinations on the more subtle functions of the blood which could not be plain to him. I will endeavour very briefly to refer to the cardinal discoveries respecting the blood which have come to light since Harvey's time. Within half a century the red corpuscles were recognised and described by Malpighi, followed in more detail by Leeuenhoek.

Oxygenation.

In 1668, three centuries after saltpetre had been utilised in explosive combination for the destruction of human life, Mayow recognised "nitre air" as the essential agent of slower combustion, and its activity in respiration and other processes in the body. "The function of breathing," says Mayow, "is merely to bring air in contact with the blood to which it gives up its nitro-aerian constituent and from which it carries off the vapours produced by the heating of the blood." Again, "The blood carries the nitro-aerian constituents to the muscles (including the heart), and their motion results from the chemical reaction in the muscle with the combustible matter contained therein." The view thus expressed by Mayow nearly two and a half centuries ago may be said to epitomise what we now know of the oxidation side of the respiratory function, and was further confirmed by Boyle in 1670, who demonstrated that the presence of air was necessary for the existence of both land animals and water animals. Although the existence of oxygen was thus predicated by Mayow and Boyle, and especially by Mayow, as necessary to life, it was not actually isolated until a century later by Priestley (1774).

The fact that oxygen forms a loose but definite combination with the hæmoglobin of the red corpuscles, and the further important fact that carbon monoxide has a preferential attraction for the hæmoglobin, and forms a more stable combination with it, are discoveries of great importance in elucidating the processes of respiration both in the lungs and in the tissues, especially the muscular tissues.

The most recent observations of Haldane and Priestley, Loewy, Zuntz, and others upon the composition of alveolar air and of venous blood, especially as regards oxygen and carbon dioxide, bring the matter up to date, showing: (1) that whilst normal arterial blood as it flows away from the lungs is within 1 volume per cent. of being completely saturated with oxygen (19 c.c. oxygen to 100 c.c. of blood); (2) after passing through the systemic capillaries the oxygen is reduced to 12 volumes per cent. (3) In venous blood the tension or pressure of the two gases O and CO_2 has been estimated by Loewy and von Schrötter as 5·3 per cent. of an atmosphere (37·6 mm. Hg) for oxygen and 6 per cent. (42·6 mm.) for CO_2 respectively. In arterial blood the tension of oxygen is about 100 mm. Hg (or 15 per cent. of an atmosphere) (Howell), that of CO_2 5 per cent. of an atmosphere (35 mm. Hg.) (4) In the tissues the relative tension of oxygen and CO_2 is for oxygen *nil*, for CO_2 50 to 70 mm. Hg. (5) The oxygen is so loosely combined as oxyhæmoglobin and so readily displaced by CO_2 that practically these gases follow the law of diffusion through membranes.

It thus becomes evident that, coincidently with the circulation of the blood, there is a respiratory circuit in lungs and tissues of the gases it contains, oxygen entering the blood at the lungs and permeating the capillaries into the tissues; CO_2 entering the blood at the tissues and permeating the pulmonary capillaries of the alveoli. The respiratory process commences in the lungs and is completed in the tissues, the remnant of oxygen returning with the venous blood being replenished in the lungs, and the carbonic acid accumulated from tissue changes escaping through the lungs to gather again as the blood reaches the tissues through the systemic capillaries, the whole function being under the watchful regulation of the medullary nerve centre. The picture only differs in its more exact detail from that so ably sketched by Mayow 250 years ago.

The presence of oxygen and nitrogen in the blood plasma is but of slight collateral importance except in morbid conditions such as those found in caisson disease both in compression and decompression.

Coagulation.

The coagulation of the blood was a phenomenon familiar to physicians from all time, and innumerable observations were made on the characters of the clot resulting from venesection and what they might portend. In alluding to the phenomena observed we must bear in mind that all the earlier and much of the later observations relate to inanimate or shed blood, or *gore*, as Harvey brusquely speaks of it.

In 1770 William Hewson, a junior contemporary and for a time a co-lecturer with William and John Hunter, made some remarkable observations on the coagulation of the blood, recognising that it was due to changes in the plasma, was prevented by some action of the vessel wall, and that outside the body it was also prevented by the presence of a neutral salt (sulphate of soda). It was Schmidt, however, who in 1861 laid the foundation of the modern theories of coagulation by isolating fibrinogen and by the discovery of the fibrin "ferment" to which the name of thrombin was afterwards applied. Hammarsten confirmed and extended his observations, which were importantly added to by the discovery by Arthus and Pages that calcium salts played an important part in the coagulating process.

Thrombin is not naturally present in the blood, but is evoked by the action of calcium salts upon an inactive precursor called prothrombin or thrombogen. Whether thrombogen exists naturally in the blood is also questioned. The theory of coagulation accepted by Professor Halliburton is that thrombogen is a substance existing in the blood plasma which in association with an activating agent called thrombokinase (which does not pre-exist but is derived from the platelets, red corpuscles, and tissue elements) and in the presence of calcium salts is converted into the active enzyme or ferment. The thrombin thus produced reacts upon a protein substance, fibrinogen, which is present normally in the blood plasma and transforms it into the insoluble, stringy material, fibrin, which entangles the other elements of the blood to produce a clot. It is assumed that for the production of thrombokinase some disintegration of the platelets is necessary, or that it is washed in the flow of blood from the tissues. These observations, complex as they are and by no means as yet fully accepted, apply, let me repeat, to inanimate blood after it has left the vessels. They also apply with some reservations to the formation of post-mortem clots in the heart and great vessels.

It was observed by Wooldridge in 1886 that thrombin as prepared by Schmidt when introduced intravenously does not produce coagulation. This little difficulty has, however, been met by the supposition that the thrombin is neutralised by an antithrombin circulating in the blood. The nucleoproteins of tissue extracts which coagulate the living blood are supposed to do so by the thrombokinase they contain, but Wooldridge has shown that a larger quantity of the same extracts causes the blood to become less coagulable.

Intravascular Thrombosis.

The coagulation of living blood to form a thrombus in a vessel is a somewhat different process of which the formation of fibrin is a comparatively late phase. An accumulation and adhesion of platelets seems to be the first thing that happens at a portion of an artery or vein which from injury or disease, usually of an infective nature, excites the coagulation. Almost immediately leucocytes collect in the mass followed by fibrinous formation which penetrates the whole, entangling red corpuscles and other elements of the blood. Whether this formation of fibrin is the result of the reaction of platelets or white cell secretion upon fibrinogen does not seem to be settled, but both appear probable. More purely fibrinous clotting of the blood may be observed within the vessels over roughened surfaces and inflammatory areas. Pure leucocytes may collect to block small vessels. Again, under certain toxic conditions the red corpuscles may adhere to form thrombi, occluding small vessels.

The mode of extension, absorption and organisation of thrombi has been fully established. The initial reason for the occurrence of a thrombus is much more obscure. It would seem that slowing of the current of the blood tends to the accumulation of platelets which normally occupy the centre of the current to the sides in the outer and comparatively still zone of the stream, and the same is known to hold with regard to the white cells. It still requires a broken or a diseased inflammatory or degenerated surface of the vessel to attract the accumulation of platelets and corpuscles, and the ultimate formation of fibrin to form the thrombus. The so-called inflammatory thrombi, whether originating in phlebitis or arteritis, are now recognised as of infective origin, associated with such diseases as rheumatic fever, influenza, enteric fever, and the like.

It would thus appear that intravascular thrombosis is a vital and not a chemical or fermentative process such as obtains in inanimate blood. It is more like the reaction of a tissue to heal a breach of surface. The thrombokinase reaction resulting in thrombosis and the formation of fibrinous layers and reticula are secondary occurrences, although of great importance in building and consolidating the thrombotic mass. In due time the thrombus degenerates, is absorbed, or rather consumed in its effete parts by phagocytic action, whilst from the vessel side it is becoming organised by the penetration of new vessels. Like many vital attempts at repair, the process has its inconveniences and dangers, but in the closing of severed or ligatured vessels and the occlusion and consolidation of aneurysms we find its value, whilst the immediate isolation of a morbid spot in the vessel by the formation of a protective clot must be of importance in preventing general blood contamination.

In septic thrombi a new element is introduced which need not be discussed here. Given a breach of surface—e.g., a degenerated aorta or cardiac valve—and the presence in the blood of bacterial organisms derived from infected surfaces—colon, bladder, gums—or absorption from without, and there is now no mystery to be explained in the occurrence of infective thrombosis from the lodgment of such organisms on unprotected surfaces.[1]

Dr. Senhouse Kirkes[2] first drew attention in 1852 to embolism or blocking of the vessels from fibrinous clots conveyed from the right or left cavities of the heart to the lungs and systemic organs respectively. And further developments of the observations have been far-reaching in pathology and clinical medicine.

COÖRDINATIVE ATTRIBUTES OF THE BLOOD.

In the fertilised protoplasm in which animal life has its beginnings there is a coördination of the formative, digestive, circulatory, and sentient functions under the ægis of nervous activation—if I may apply so modern a term to so old a service—that maintains the autonomous individuality of the organism. This coördination of process is sometimes spoken of as a species of chemiotaxis, using the term in its widest sense. In the course of evolution and in that brief epitome of it that proceeds *in utero* in the more advanced types of animal life separate organs representing each function are gradually differentiated. The same correlation of function, however, must still be maintained, and the *consensus partium*, as it has happily been expressed, by which this correlation is preserved under conditions of greater elaboration is effected through the medium of the circulation by means inconceivable at the time of its great discoverer, but still, as in the primitive plan, under the control of the nervous system. The principle of every cell being an individual organism was instilled into my mind in my earliest student days by a remarkable man, Professor Grant, of University College, who held the chair of comparative anatomy in the middle third of the last century. In 1846 Wharton Jones, another pioneer of blood biology now forgotten, had discovered the amœboid movements of the white cells in fishes, and Davine soon afterwards found the same in human blood.

---

[1] Professor Welch's account of Thrombosis in Vol. VI. of Allbutt and Rolleston's System of Medicine is the most lucid and comprehensive, and although five years old, as yet, I believe, requires no material modification.

[2] Transactions of the Royal Medical and Chirurgical Society, vol. xxxv.

Many years before the doctrines of cellular pathology of Virchow, of the wandering cells of Cohnheim and their phagocytic function as discovered by Metchnikoff were under discussion, Professor Grant thus interested the young minds of the few who would attend his class in the cells of the blood. He pointed out that they were, as the other cells of the body, living entities, carried here and there in the highways and byways of the liquid tissue of which they formed a part; that each cell earned its own livelihood within the limits of its environment, absorbing its own nourishment and secreting its own products; and that, moreover, these cells were, like Autolycus, "snappers up of unconsidered trifles," such as may be effete and strange in the vital stream—flotsam and jetsam of the tissues, or foreign bodies introduced from without.

These two conceptions—(1) that the blood is a liquid tissue the formed elements of which have their own autonomous vitality, and (2) that it is the chief means by which the *consensus partium*, so simple in the protoplasmic organism, is maintained in all the future complex developments of that organism—may be regarded as the main principles which underlay all the discoveries established by the brilliant researches of modern observers in the vital chemistry and biology of the blood. *Phagocytosis* is perhaps the factor around which the processes illustrative of the first principle centre; *internal* secretion that by which the second principle is best illustrated.

I can do little more than enumerate these discoveries. I cannot even name—except here and there—the workers who have brought them about; they are all well known and for the most part still living amongst us, many of them Fellows of this College, still searching out the secrets of nature by way of experiment in the topmost branches of the tree of knowledge rooted in Harvey's discovery. Some have suffered, but, like Harvey, have outlived the obloquy cast at them by ignorance and slander.

CHEMICAL ATTRIBUTES OF THE BLOOD.

The structure and function of the blood is a subject too vast to be touched upon save in a very elementary manner. It is a tissue of which the cellular elements, as with other tissues, are beings with their appetites and antipathies, earning their living "on their own" in their plasmic environment; the difference being that the environment of the blood cells is liquid, a vital, an ever-flowing stream, whilst the cells of the fixed tissues are dependent upon such portions of the plasma as are conveyed to them by the vessels of their connecting framework.

The blood thus contributes to and partakes of all organic function, and in the composition of its plasma there have been recognised, identified, and isolated—(1) substances called proteins destined for the body nutrition; (2) products of metabolism *en route* for removal; (3) salts which attend and facilitate both processes; and (4) certain other substances, neutral bodies, ferments, opsonins, antibodies, too numerous to speak of individually, some of which, as fibrinogen, can be identified and isolated; others—the opsonins, the antibodies, and some of the ferments—are discoverable only by their effects, some of them somewhat supposititious, like the meat-roasting quality in a jack, humorously alluded to by our quondam Fellow, Arbuthnot, in his amusing skit on the learned disquisitions of his time respecting the seat of the soul.

Harvey's tribute to the blood as the very essence of life is thus scarcely exaggerated; it is the tissue which has relations with every other tissue and process in the body by virtue of its fluidity and the pressure of its penetration. It gives and receives, and yet in health is ever the same. Its intimate concern in all the relations of life may be further revealed in the additional features I have yet very briefly to mention.

The whole subject of the chemical reactions of the blood and the means by which the uniformity of its reaction and quality are maintained has been most recently and fully discussed by Dr. F. Gowland Hopkins in the Oliver-Sharpey lectures of this year.[3] Its uniform reaction under the imbibition of large quantities of acid and alkaline fluids and acid and alkaline-producing foods is as truly remarkable as its constant temperature in health. It is suggested that whilst the lungs are chiefly concerned in controlling the hydrogen ions due to carbonic acid, the kidneys are concerned with those due to other acids, chiefly lactic acid, formed in the muscles, with the result that the mean reaction of the blood is normally adjusted with great exactness.

Cholesterin is an important constituent of the blood, or rather an important agent circulating in it intimately concerned with cell life, which is now recognised as an essential and vivifying constituent of all cells. Its presence in the blood plasma may be only *en route* to its destiny in cell formation. With the disintegration of cells which takes place largely in the liver their cholesterin is set free to be reabsorbed and utilised in the generation of new cells.

Many of the ferments discovered—mainly by their effects—in the blood may perhaps be regarded, somewhat crudely from a physician's point of view, as to some extent contaminative, having their source as overflows from organic function (especially of the digestive cells) and of little or no importance in the vital mechanism, unless they should be in excess from accumulation owing to defective elimination when they act as poisons.

Abderhalden draws attention to the protective action of certain ferments in defending the body from the injurious effects of organisms and chemical substances which are foreign or "disharmonious" to the blood and tissues. He finds that the introduction into the blood of disharmonious substances results in the appearance of ferments which were not previously present, but which possess the property of breaking down the foreign substances into simpler bodies with which the cells are accustomed to deal. He regards such ferments as modifications of the normal metabolic processes of the cells of the tissues or blood, and would thus seem to sanction the view I have been advocating that the cells of the body are equipped for their own defence as well as their own nutrition, and may be principally concerned in the secretion of "opsonins" and "antibodies" appropriate to their needs. The first and second lines of defence provided by the gastro-intestinal and hepatic cells are described by Abderhalden, and the plasma derives from the tissue and blood cells the ferments required for further dealing with disharmonious intruders and rendering them so far disorganised as to be amenable to phagocytic action.

---

[3] THE LANCET, June 6th (p. 1589) and 13th (p. 1661), 1914.

Abderhalden pushes his argument to the formulation of a diagnosis of pregnancy, carcinoma, and some other diseases by the recognition in the blood of ferments antagonistic to the proteins yielded by the placenta and carcinomatous growths respectively. No doubt his work will be subjected to careful scrutiny and will stimulate new researches. The question of the production of antibodies to meet other extrinsic infections he has not discussed.

INTERNAL SECRETION.

With the recognition of the fact that nearly every glandular organ in addition to its proper secretion discharged through its duct yields also to the blood a secondary secretion peculiar to itself, a large field of interest and inquiry has been opened up to physiologists and many previously obscure phenomena have become more clear to physicians. Herein may be found an illustration and perhaps an explanation of the correlation of organic function which has been spoken of as the *consensus partium*, through the messages—mostly chemical—communicated by each organ to the controlling nerve centres; in a word, the "chemiotaxis" of the embryonic germ is maintained through the medium of the blood between differentiated and distant organs.

Professor Berthold, of Göttingen, in 1849, first showed the existence in the testicle of this second function of contributing of its essence to the blood, and it was Claude Bernard who in 1855 first applied the term "internal secretion." But Brown-Séquard's experiments upon the testicular internal secretion gave the impetus to all the physiological and therapeutic work that has followed. Brown-Séquard's experiments (1889) and the therapeutic measures to which they pointed led to false hopes and to abuses of an unworthy kind which for a time brought some discredit upon them. Their value in the treatment of premature senility, climacteric disturbances, and of some mental ailments was in a measure established, though with exaggeration, but their chief importance rested upon the further researches they initiated with regard to generative and other glands. The therapeutic measures they instigated are used extensively, though somewhat surreptitiously, at the present day.

Investigations on the Ductless Glands.

The ductless glands were the first objects of this further inquiry, and in rapid succession there appeared important results from the physiological experiments and clinical observations of Schiff, Sir W. Gull, Miller Ord, Kocher, Victor Horsley, and others upon the function of the thyroid gland and the parathyroids. In 1856 Schiff showed that the thyroid gland was essential to life. In 1873 Sir W. Gull described the condition which he named the "cretinoid state in adult life in women," which was further studied by Dr. Ord, who more fully described the clinical features of the disease, which he named myxœdema and associated with atrophous conditions of the thyroid gland. A swelling of the gland of a peculiar kind had long been associated with exophthalmic goitre, and in 1882 Reverdin and Kocher discovered that the removal of the gland for this disease resulted in symptoms described as those of "cachexia strumipriva," which were of the nature of myxœdema. Similar symptoms were artificially produced in monkeys by the removal of the healthy gland, by Horsley in 1891. In the same year Dr. Murray, then of Newcastle, introduced the injection of thyroid extracts for the successful treatment of this disease, on the same principle as Brown-Séquard had used allied extracts for senile affections. Thus, and by further researches at other hands, the relations of myxœdema, cretinism, Graves's disease, and operative myxœdema or cachexia strumipriva to the thyroid gland have been fully established, and a new era of therapeutic treatment invaluable for the relief of human suffering has been opened up. More complex relations have been found in the internal secretions of the parathyroids to other organs, especially the pancreas.

The relation of thyroid essence taken up by the blood to cardiac innervation and to general metabolism is being carefully investigated, and has been so far established as to instigate various measures of therapeutic value.

Another great Guy's physician, Addison, first discovered (1855) the importance of the suprarenal glands and described the symptoms of a certain diseased condition of them which is known by his name. This discovery led to a chain of observations by Brown-Séquard, by Kölliker, and others until, in 1894, Schäfer and Oliver established the connexion between the suprarenal essence, and especially that of the medullary portion and blood pressure. Addison had recognised as a marked feature of his disease the notable depression in the pulse tension. Schäfer and Oliver discovered as a chief function of the suprarenal bodies the maintenance of blood pressure, and initiated an important and now well-known method of treating suprarenal disease and established the value of extracts derived from the gland as a sympathetic nerve stimulant. Further researches have shown that this extract especially affects circular organic muscle, including the heart and vessels, and there are many collateral effects still under investigation.

On similar lines interest attaches to the contribution of the pituitary body to the blood, its function in health, its effects under diseased conditions, and the therapeutic value of extracts derived from certain portions of it. The field of investigation has greatly widened, and the pancreas, the kidneys, the liver, and the gastro-intestinal cellular digestive tract have successively been found to yield not only their secretion into the ducts and channels with which they are properly connected, but a secondary internal secretion contributed to the blood.

Importance of Internal Secretions.

Professor Starling and Dr. Bayliss, to whose researches a large portion of our knowledge respecting the internal secretions of the digestive tract especially is due, have applied the term "hormone" to these secondary glandular products, and the term will probably soon be used to include all internal secretions. It is important to recognise Professor Starling's distinction of hormones from other materials or influences in the blood, such as antigens arising from toxins, ferments, &c., each with its corresponding antibody. Hormones readily pass through the capillary vessel walls, and, having effected their purpose, they undergo rapid destruction by oxidation or otherwise and are known no more. It may be the condition of greater simplicity of composition, lighter specific gravity, and greater diffusibility attributed to these chemical essences that cause these hormones to get into the blood, whilst the more obvious organic secretions escape through ducts to their destination.

It would be difficult to exaggerate the interest and importance of these hormonic contributions to the blood from the different organs and tissues. Quite unobservable in their course, they yet convey messages and instructions to the nerve centres leading to vaso-motory relaxation or constriction of the capillary areas whence they proceed. In this way they correlate and regulate growth and function, at the same time preserving that *consensus partium* so comparatively easy in the simple amœboid structure. Here is a great function of the circulation, undreamed of by Harvey, in distributing these agencies, which is as imperceptible to our unaided comprehension as are the infinity of living particles in the clear atmosphere until illumined by a sunbeam, or the thought waves teeming in a crowded assembly. By their effects only can we gauge them, and only by the deepest and most subtle researches—by experiment upon their effects—can we learn these secrets of nature.

> Strange is it, that our bloods,
> Of colour, weight, and heat, pour'd all together,
> Would quite confound distinction, yet stand off
> In differences so mighty.[4]

The mental side of these phenomena is of great but at present, for the most part, speculative interest to the psychologist, the alienist physician, and the criminologist. In the phenomena of hysteria and its border-line manifestations, of insanity and of criminal impulses, as well as in the controlled impulses that account for character and discipline, we may find interesting fields for the study of the effects of internal secretions as they here and there emerge to consciousness from their sphere of automatic action.

DEFENSIVE ATTRIBUTE OF THE BLOOD.

The last attribute of the blood is that of defence against attacks, mainly infective, upon the organism, an attribute which eventuates in the establishment of immunity to infective diseases. After the experience of an infective illness the blood becomes more tolerant of that particular poison, whilst its defensive forces are strengthened and the poison influence is weakened or altogether neutralised. Thus immunity arises.

The Establishment of Immunity.

The methods of blood defence and the modes by which immunity is established are still matters of considerable controversy, and the various views expounded are often expressed with a vocabulary which obscures rather than renders more clear the arguments of the disputants. There are, however, two main contentions or schools of opinion: the one with which Professor Ehrlich is perhaps most identified, which regards the bactericidal influence of the blood as chemical and residing in the plasma; the other, held by Metchnikoff and his followers, regarding it as resident primarily in the cell elements of the blood and of certain tissues. It has been shown, mainly by the work of Sir A. Wright, that (as in most controversies) the essentials of both views enter into the truth of the matter.

From my earliest training to recognise the predominance of cellular over liquid plasmic processes, I must confess a strong prejudice in favour of the opinion of Metchnikoff that the leucocytes of the blood chiefly, and perhaps the endothelial cells of blood-vessels and serous spaces and the cells of the tissues to a greater extent than he would admit, are the source of such agents, doubtless mainly chemical, as are found in the blood plasma as alexins, ferments, antibodies, immune bodies, opsonins, or what not. These agencies, by whatever name they may be known, reinforce the general qualities of the blood serum in the attack upon living and for the digestion of dead foreign bodies, which are then consumed by the phagocytic action of the leucocytes and the other cells named. On the other hand, bacterial and protozoic organisms on their side, with their infinite productivity and the secretions they yield, may well be conceived to be capable in many instances of overwhelming the defensive action they at first excite. This is how the matter crudely presents itself to the mind of an average physician after labouring through as best he can the intricate and wonderful work of those numerous bacteriologists who have cast such brilliant light on the intimate biochemical processes of the blood. It is also readily to be understood how the local introduction of minute quantities of "disharmonious" substances, such as bacterial toxins, may excite the production locally of antibodies the absorption of which into the general circulation will reinforce the defensive qualities of the serum. We must not forget, however, that it is a natural process of defence, a tendency to immunity, which is excited by all bacterial and protozoic infections, the exact nature of which it has been the primary object of all these brilliant researches to show, and that it is the observation and study of this natural process which has prompted the use of artificial measures for its assistance.

Vaccine Methods of Treatment.

The immunity gained by an attack of certain specific diseases against further assaults has long been known to physicians: how mild attacks of small-pox, whooping-cough, scarlet fever, dissection wounds, will protect, at least for a time, often the lifetime, from further attacks. Lady Mary Wortley Montagu and Edward Jenner were pioneers in interpreting rightly this natural lesson in immunity, and the exact inquiries of modern observers have thrown so much light upon the processes concerned as to have established on scientific lines vaccine methods of treatment in many acute specific diseases and of analogous methods in some chronic diseases. It was Pasteur who, in 1880, revived the question of immunity on experimental lines in his observations on chicken cholera, and suggested the possibility of establishing artificial immunity in certain diseases. Within the lifetime of the youngest here diphtheria, enteric fever, tetanus, and plague have lost half their terrors.

The applicability of knowledge gained respecting immunity processes is now being utilised in certain chronic infective diseases, notably tuberculosis and perhaps arthritis. All practical physicians have long been aware of the fact that an attack of tuberculosis or repeated attacks having resulted in a chronic passive fibroid lesion, the patient if able to endure such lesion without fresh assault for a certain time acquires a very considerable, even a permanent, degree of immunity, and may die in later life from disease of a quite different kind. It is now recognised that such patients acquire and perhaps retain their immunity through the absorption of successive doses of tuberculin taken up by the blood in its course through their passive or indolent lesions. They are in possession of an inoculate, a source of vaccine, in the remnants of quiescent morbid tissue left behind by the acute disease. Thus are they in a measure fortified against fresh infection. This view, which would seem to hold good with regard to tuberculosis and perhaps syphilis, may in a more subtle manner hold good also with regard to remnants left behind by the acute specific fevers, as so coarsely illustrated by the effect of inoculation in small-pox; such a hypothesis is at least interesting in bringing into line the doctrine of immunity with the phenomena of internal secretion already discussed.

---

[4] All's Well that Ends Well, II., 3.

Advantage has been taken of this knowledge in the rational treatment of tuberculous patients by retarding or exciting the circulation through their lesions by regulated exercises. A warning must attend these observations—viz., that some of these people have their leucocytic functions sensitised by such autogenous stimulation, and are thereby rendered unduly excitable to further stimulation—they are anaphylactic—in a greater or less degree, and tuberculin inoculations are apt, unless given with the greatest caution as regards dosage and repetition, to induce a recurrence of negative phases or periods of paralysed resistance very inimical to the patient's prospects. I cannot say that I have ever observed tuberculin vaccine given three times a day after meals, after the manner of the Court physician in the "Doctor's Dilemma," but I have often seen it given on unsuitable occasions and in recklessly repeated doses in entire ignorance of the intimate history of the disease and with disastrous results. The necessity of a period of restful quietude after any administration of tuberculin is further emphasised by the above considerations.

Conclusion.

We have seen how heart and pulmonary mechanism are subordinate to the circulation of a vital stream which, so constant in all its physical aspects, so infinite in its attributes and adaptations, dominates all the functions of life. Might not Harvey quote Leviticus—"for the life of all flesh is the blood thereof"—with even greater conviction to-day?

I have yet, Mr. President, one duty to perform, and that is to exhort the Fellows and Members of the College to continue their endeavours for the advancement of the College in learning and general prosperity. It is impossible to record the numberless gifts to the College since Harvey's time; gifts of learning, gifts to the library, gifts of valuable and interesting documents relating to the College, gifts for research, gifts for hospitality. In the past year such gifts have been continued and were recorded in your address recently published. Harvey's further exhortation to the Fellows was that for the honour of the profession they should continue "in mutual love and affection amongst themselves, without which neither the dignity of the College can be preserved, nor yet particular men receive that benefit by their admission into the College which else they might expect, ever remembering that *Concordia res parvae crescunt, discordia dilabuntur.*"

I gratefully acknowledge the kind help I have received from my colleague Dr. R. A. Young in the literature, especially that relating to the blood; and also my great indebtedness to Miss E. Parry for much assistance in revising the proofs and in verifying the references, only a small fraction of which are annotated in the text.

TRAUMATIC TETANUS.

By M. H. GORDON, M.A., M.D., B.Sc. Oxon.,
ASSISTANT PATHOLOGIST TO ST. BARTHOLOMEW'S HOSPITAL.

The appearance of tetanus among those wounded during the recent fighting on the continent and the possibility of further cases seemed to make it desirable to look up the literature of this fortunately rare disease, and also to place on record any personal experience, however small, of its bacteriology. The following notes, incomplete though they necessarily are, may possibly be useful. I am encouraged to this course also by the fact that acting on a happy suggestion of Dr. J. H. Drysdale I have consulted the monograph on tetanus for which the late Professor A. A. Kanthack received the Jacksonian Prize in 1895. This essay is kept in the library of the Royal College of Surgeons of England, and consists of two volumes, the second of which contains a large number of original photographs and illustrations. I have found this essay of very great value not merely because it contains a review of the literature up to that date, but chiefly because it embodies the result of a year's original research on tetanus by Kanthack. Accordingly, I have drawn upon it largely in the following paper, as also upon the recent comprehensive reviews of Eisler and Lingelsheim.

Characters of the Disease.

Clinical diagnosis.—It is unnecessary to go into detail with regard to the classical symptoms of tetanus—trismus, rigidity of the muscles of the neck, opisthotonos, &c.—for they are unmistakable and thoroughly well known. It is of interest, however, to note that whereas in man and the horse, in whatever region the site of the superficial wound may be, the earliest muscles to be affected appear to be those of the neck and jaws, in other animals the disease generally begins as a local tetanus—i.e., the muscles nearest the site of inoculation are affected first, and the disease spreads from that point in a definite order. Sawamura, whose work is quite recent (1909), recognises three kinds of tetanus: tetanus ascendens, tetanus descendens, and mixed tetanus.

In tetanus ascendens the local muscles are affected first, next the tetanus spreads up the limb, then to the opposite limb, and finally up the trunk. This is the form commonest in experimental animals after subcutaneous or intramuscular injection. It is possible, however, that this type is not so rare in man as may be supposed. Witness the case of M. Nicolas, laboratory assistant to M. Courmont and M. Doyon, who accidentally introduced into his thenar eminence the point of a syringe which had just been used for the injection of an animal with tetanus toxin. Although he received only a trace of toxin, Nicolas, after an incubation period of four days, developed tetanus, and the contractures began in the inoculated hand, then spread up the arm and became generalised. After a severe attack lasting 41 days he recovered. This, therefore, was a case of ascending tetanus, and it is to be hoped that a sharp look out will be kept for any stiffness of the local muscles, for Sawamura has shown experimentally the great value of a local intraneural injection of antitoxin at this stage of the disease. Tetanus descendens appears to be the commonest form in man and the horse. The muscles of the jaw and neck are first affected, and then the disease spreads down the body. It is of graver significance than tetanus ascendens. In mixed tetanus both the above forms occur.

Prognosis.—There are few diseases in which we have such sure knowledge available for the purpose of prognosis. The patient's chance of life depends upon (1) the incubation period, (2) the rapidity of onset and severity of spasms, and (3) the duration of the disease. Of these points (1) is the most important and (2) comes next. In the words of Kanthack, "fatality is in direct proportion to rapidity of onset, and inversely proportional to the duration of the disease." It is perhaps permissible to illustrate this point by an example. Rose collected over 700 cases of tetanus. He found the mean mortality to be 88 per cent. Of those developing tetanus during the first week 91 per cent. died, during the second week 81 per cent., and during the third week 52 per cent. Richter and Poland, who also investigated this matter, have published similar figures. Richter has stated, by the way, that of 717 cases of tetanus contracted on the battlefield 80 per cent. died. In 1892 Rotter drew attention to the fact that tetanus cases with an incubation period of less than ten days are extremely severe, and Tilmann in 1907 emphasised the same point. Cases in which the march of the symptoms is rapid and the spasms severe are very fatal. As regards duration, it would seem that if the patient lives two days after the tetanic symptoms have begun, his chances of recovery are greatly improved. In this connexion it is of interest to recall the aphorism of Hippocrates: "Such persons as are seized with tetanus die within four days, or if they pass these they recover." This dictum would seem to be in the main true to-day, if a trifle optimistic.

As will be described later on, some of the virulent bacteria frequently associated with the tetanus bacillus in the wound have a way in certain cases of invading the patient even when the long range effects of the tetanus bacillus have abated.

The Bacteriology of Tetanus.

Isolation of B. tetani (a) from earth.—The cause of tetanus is a bacillus which Nicolaier found and described in 1884 in animals rendered tetanic by inoculation with particles of earth. On this subject Kanthack writes as follows:—

> In attempting to obtain it from earth we must first make sure that the sample of earth actually contains the tetanus micro-organism. This can be done only by means of animal experiments, mice lending themselves best for the purpose. If the mice become tetanic then we may proceed with the separation of the bacillus from the earth by suspending it in broth to which 1–5 per cent. carbolic has been added. Place these tubes now at 70–80° C. for one hour and then incubate them anaerobically at 37° C. Next day heat again, and on the third and fourth day again. It is by no means easy to separate the tetanus bacillus from soil; the ease with which it can be done seems to depend on the number of spores present. If the bacillus of malignant œdema is present plates must eventually be made, since this bacillus is both anaerobic and sporogenous.

(*b*) *From pus.*—In attempting to isolate B. tetani from mouse or man the pus or local scrapings are distributed in carbolised broth and treated in the same way as in the case of the earth. After the fourth day by means of a capillary pipette a number of grape sugar broth tubes are liberally inoculated and kept anaerobically in Buchner's tubes. After a few days the tubes must be examined microscopically, and if any contaminations are present the heating must be repeated until eventually we succeed in obtaining pure cultures. This is a certain method of obtaining the tetanus bacillus from pus or tissues containing it, provided no other sporing organisms are present which are also anaerobic. If such occur then we must plate out on formate agar or on glucose gelatin. The surface growth of a pure culture of B. tetani on ordinary peptone broth agar containing 0·5 per cent. of sodium formate shows up after 24 hours at 37° C. anaerobically as a series of small raised punctate transparent colonies. These colonies slowly increase in size, but always retain their transparency. This is important, for any distinctly opaque colony is almost invariably a contamination. So characteristic, says Kanthack, is the growth on formate agar that "I always use this culture to satisfy myself as to the purity of my stock material." Cultures of B. tetani in broth or gelatin maintain their vitality at room temperature for as long as six months.

The Bacteriological Diagnosis of Tetanus in Man.

(*a*) *By film preparations.*—Film preparations of the local pus have as a rule very little value for establishing the presence of B. tetani owing to the fact that this bacillus appears only sparsely in the local material and does not show up there in the characteristic drumstick shape, but chiefly occurs in the form of slender rods. Kitasato noticed that the bacillus disappears locally, and Vaillard and Vincent demonstrated that there was no appreciable multiplication, and that even in fatal cases local films might fail to show the presence of the tetanus bacillus so soon as 14 hours after inoculation. The value of film preparations, therefore, in man is mainly to see if a mixture of organisms is present suggestive of earth infection. Tetanus cases are probably in all cases primarily a spore infection. Besides streptococci or staphylococci, coliform bacilli may be found in the wound, and in the worst cases the well-known large Gram-positive anaerobic spore-bearing bacillus associated with emphysematous cellulitis is present.

(*b*) *By culture.*—Vaillard and Vincent ascertained that, in spite of the local rarity of the tetanus bacillus in films, it could always be recovered locally by culture in the case of animals that subsequently developed tetanus. It would appear advisable, therefore, to make attempts to isolate the tetanus bacillus by culture in cases where the presence of the micro-organism is suspected or proved. An even more certain way, however, and a much quicker one in the present state of our knowledge, is to inoculate a mouse with material from the wound. In positive cases the mouse becomes tetanic within three days; though it would appear that the disease cannot be indefinitely transmitted from mouse to mouse by inoculation with their local pus; after the third transference the disease may fail to pass.

The Importance of the Associated Bacteria in Human Cases of Tetanus.

As long ago as 1891 Vaillard and Vincent showed that when freed of adhering toxin either by washing or by heat neither B. tetani nor its spores produced tetanus in animals by simple inoculation. They found, however, that the toxin-free bacillus or spore could produce the disease if they bruised the tissues locally by pinching them with a forceps, also if they simultaneously injected either lactic acid or another micro-organism, such as B. prodigiosus or even its filtrate. These experiments are generally held to show the importance of bruising and also of a mixed infection in the genesis of tetanus. There is reason for doubting, however, if it is even now clearly realised how very important the associated bacteria may be. It has been stated before that the commonest cause of tetanus is infection of a wound with earth, and this, of course, always contains a variety of bacteria and spores. The earth of chief repute for producing tetanus is that soiled with the manure of horses and cattle. It is of interest in this connexion to note that while tetanus was found by Pizzini to be present in human fæces in 5 per cent. of the cases examined by him it was found by Sanchez Toledo and Veillon to be present in the excrement of cattle in 50 per cent. of the cases. Now the dung of horses and cattle, as also of man, constantly contains a large Gram-positive anaerobic spore-forming bacillus in very considerable numbers, and owing to its abundance in horses' excrement this same micro-organism is constantly present in street dust. On inoculation subcutaneously into animals the microbe in question produces a spreading emphysematous cellulitis quickly followed by death from septicæmia. This micro-organism or varieties of it are known by a plurality of names —e.g., vibrion septique of Pasteur, B. aerogenes capsulatus of Welch, B. enteritidis sporogenes, and B. perfringens. Spores of it are constantly present in large numbers in street dust, and quite a considerable proportion of cases of street accidents in which there is much laceration of the skin and subcutaneous tissues succumb to infection with this micro-organism. Now the point which I wish to emphasise is this. In three out of the four fatal cases of tetanus which I have had the opportunity of examining both before and after death at St. Bartholomew's Hospital during the past three years this bacillus of Welch was present in the local pus during life. In two of these fatal cases of tetanus the heart's blood of the patient contained the bacillus of Welch in pure culture and in very large numbers. In the first of these cases, a gardener, aged 27 years, with crushed fingers, the incubation period of his tetanus was 16 days; the tetanus disappeared after intracerebral injection of tetanus antitoxin, but in spite of the removal of his crushed fingers and the abatement of his tetanus an emphysematous cellulitis spread up his arm and he died on the fifth day from the onset. Death in this case was, I feel certain, due to Welch's bacillus. In the next case, a female aged 52 years, who fell out of a cart on a country road as the result of being run into by a motor-car, and sustained a compound fracture of her right radius and ulna, the incubation period of the tetanus was six days; the degree, however, was not intense. The patient died at the twenty-seventh hour, and I have personally little doubt that the septicæmia from Welch's bacillus, proved at the post-mortem examination, was the chief cause of her death. In the third case, a labourer aged 18 years, who ran a pitchfork into his foot, the incubation period was seven days, and the duration of life after tetanic symptoms began four days. Here the local pus showed streptococcus only as the associated micro-organism, but post mortem this streptococcus was found to be present in large numbers in the heart's blood. In the fourth case, a boy aged 10 years, with a compound fracture of his tibia and fibula sustained in a street accident, the onset of tetanus was on the sixth day; the spasms were very severe, and he succumbed within 24 hours. Welch's bacillus was present in the local pus, but this patient's heart's blood was sterile.

This personal experience of tetanus, therefore, limited though it is, has led me to attribute a very important rôle to the associated bacteria, particularly in fatal cases. It seems probable that the explanation of the difference in prognosis according to the length of the incubation period to which reference has been made is directly due to the association of B. tetani with other virulent bacteria of which the most important is the anaerobic bacillus of Welch. The bearing of this observation upon the rational treatment of tetanus will be discussed later.

Tetanus Toxin.

When Nicolaier discovered the tetanus bacillus at the site of inoculation in his tetanic animals and found that it did not become generalised throughout the tissues he suggested that this microbe was capable of secreting *in loco* a soluble poison the diffusion of which gave rise to the symptoms. The correctness of this view was proved in 1890 by Knud Faber, who showed that the bacterial-free filtrate obtained from a broth culture of B. tetani was capable of producing all the symptoms of tetanus. Since that date a very large amount of work has been done on tetanus toxin, which appears to be the most poisonous substance at present known. Hallock Park brings this point out by the following figures quoted from Lambert. It is computed that the fatal dose of concentrated dried toxin for a man of 75 kilogrammes would be 0·23 milligramme. As the fatal dose of dried cholera venom would be 4·38 milligrammes (Calmette), of strychnine 30–100 milligrammes, and of anhydrous prussic acid 54 milligrammes, the appalling strength of tetanus toxin can readily be appreciated. Tetanus toxin is readily soluble in water, is precipitated from the broth by alcohol, and is not dialysable. It is destroyed by exposure to 60° C. for 20 minutes, or to 65° C. for five minutes, and is attenuated by exposure to light and air at the room temperature. It does not appear to be harmed by the addition of 0·5 per cent. carbolic acid, which is sometimes added to it as a preservative. A destructive action, however, is exercised upon the toxin by iodine trichloride, by hydrogen peroxide, by potassium permanganate, or by organic oxidases extracted from the liver, spleen, or kidney. Tetanus toxin has been shown by Ehrlich to contain a hæmolysin as well as its more important constituent, tetanospasmin.

Path of the Toxin.

The *modus operandi* of tetanus toxin upon the central nervous system has possessed a great fascination for the experimental mind. At first it was suggested that the toxin merely increased irritability of the reflex arc, but Autokratow in 1892, and later Gumprecht, disposed of this view by showing that section of the posterior roots of the nerves supplying one limb failed to prevent the appearance of tetanus in that extremity. This experiment proved that tetanus toxin was a direct motor poison. Marie, however, in 1897 appears to have been the first actually to demonstrate that tetanus toxin was absorbed and carried from the site of inoculation by the local nerve trunks. One of the most convincing experiments establishing this neural conductivity of the toxin is that of Meyer and Ransom, who showed that the minimal lethal dose of toxin for an experimental animal is less when injected intraneurally than when given intramuscularly. In 1898 Wassermann and Takaki published their classical experiment showing that tetanus toxin when brought in contact with an emulsion of normal brain in suitable proportions *in vitro* becomes inactivated, and that an emulsion of cord has the same capacity, though to a less degree, while emulsions of other organs have no such value. This toxin-binding capacity appears to pertain to the grey matter rather than to the white, and emulsions of cortex are more active than those of the basal ganglia. When the emulsion is boiled it loses its activity, and the chemistry of the reaction does not yet appear to have been worked out. Interesting though this demonstration of the specific affinity *in vitro* between the cortical nerve cells and tetanus toxin be, the fact must not be lost sight of that (as Roux and Borrel showed) the injection of tetanus toxin directly into the brain of a living animal is followed by remarkable psychical changes, epileptiform and tetanic convulsions, polyuria, and death. Thus while an emulsion of cortical cells absorbs tetanus toxin *in vitro*, the whole brain of the animal fails to protect it *in vivo*.

Marie, moreover, found that the subcutaneous injection of cerebral emulsion failed to protect a living animal against tetanus toxin. Intimate contact, therefore, between the nervous elements and the toxin is indispensable for the success of the binding phenomenon. To return, however, to the path of the toxin. In 1901 H. Meyer showed that it was possible to recover tetanus toxin from the local peripheral nerve supplying the part infected. In 1902 Marie and Morax published a brilliant piece of experimental work in which they proved that tetanus toxin travels upwards to the central nervous system not so much by capillaries of the nerve trunks as by the axis cylinder and its peripheral terminations. They found, further, that while the toxin flows upwards in the axis cylinders to the nerve cells in the cord, it does not flow in the reverse direction—in other words, there is only a centripetal flow. The experimental work of Meyer and Ransom also indicated this path of the toxin *viâ* the axis cylinder process. Once again, however, it must be borne in mind that the nerves are not the sole route by which tetanus toxin can be absorbed. This is forcibly shown by an experiment of Sawamura, who found that where a fourfold fatal dose of toxin (as estimated by intramuscular injection) was injected into the muscles of the hind leg of a rabbit, tetanus ascendens invariably followed; whereas when this same dose was injected into the tip of the toe of the animal, not tetanus ascendens, but tetanus descendens was produced. The explanation which Sawamura gives is that in the first case the toxin is rapidly absorbed by the numerous nerve endings in the muscle, runs up the axis cylinders to the motor cells in the cord, and produces first a local tetanus, then a tetanus ascendens; whereas in the tip of the toe, which is a muscle-free region, the toxin is absorbed by the lymphatics, whence it passes into the blood stream, gains the central nervous system, and so gives rise to tetanus descendens without producing local symptoms.

Antitoxin.

While tetanus antitoxin has been a brilliant success when applied prophylactically, and its efficiency in this sense is beyond question, there is no doubt that up to the present its employment after the onset of tetanus has proved disappointing. Nor is the reason for this far to seek. A view frequently taken is that by the time the patient's symptoms have developed sufficiently to place the diagnosis of tetanus beyond all doubt he is too often beyond remedy. The poison has reached his nerve cells and the unholy matrimony has been completed.

But before we take this pessimistic view with regard to the clinical application of tetanus antitoxin, it is well to consider briefly the available evidence on the matter under two headings. 1. The view of those who have gone into the remedial value of tetanus antitoxin. 2. The experimental evidence showing what can be done in the way of recovering animals from tetanus toxin.

1. One of the most careful and impartial investigations concerning the value of tetanus antitoxin after the onset of the disease is the paper by Kanthack which appeared in the *Medical Chronicle* during 1895. The conclusion which he came to was that "the serum treatment has not actually changed the prognosis in acute and serious cases. I believe that in milder cases it lessens the spasms, the pain, and the distress, and that apparently it has reduced the mortality in such cases, but to what extent we cannot tell until we are in possession of a larger number of cases, and until we are certain that all cases are published." This view is also the one which appears to be generally held by surgeons at the present time.

2. It is doubtful, however, if the remarkable experiments of Roux and Borrel, published three years after Kanthack wrote the above words, have received the universal consideration which they deserve. It has been already stated that Roux and Borrel produced tetanus by intracerebral injection of the toxin. They next demonstrated that this cerebral tetanus was not prevented by previous subcutaneous injection of antitoxin—even though the rabbit's blood contained abundance of antitoxin at the time, the intracerebral injection of toxin gave rise to tetanus. Their most striking experiment, however, was the following one. They gave to each of 20 guinea-pigs in the hind paw a dose of toxin fatal in about 70 hours. Eighteen hours later all the guinea-pigs had rigidity of the hind paw. By the twenty-fourth hour they were all tetanic. The 5 largest guinea-pigs were kept as controls; they died from the sixty-seventh to the seventy-fourth hour. Three of the guinea-pigs were injected subcutaneously with antitoxin; they died from the sixty-fourth to the seventy-second hour. The 12 remaining guinea-pigs had a small dose of antitoxin introduced intracerebrally—two drops into each hemisphere. In all of these animals the tetanus was arrested, the contractures remained limited to the paw, or to the two hind legs according to the hour of intervention. A month later the guinea-pigs were well, but the contractures still persisted. The conclusion which Roux and Borrel came to as the result of this and other experiments was that "a few drops of tetanus antitoxin in the brain cure tetanus better than large quantities introduced into the blood or under the skin. It is not sufficient to give the antitoxin; it must be introduced in the right manner. There is a point in the disease, however, beyond which antitoxin is of no avail in whatever fashion it is employed. The intracranial injection lengthens the period of efficacious treatment."

The further information which has been obtained of tetanus since this paper of Roux and Borrel was written has brought nothing to controvert the value of their work, but has rather confirmed it. The proof which has since been furnished that the axis-cylinders of the peripheral nerves are the main conduit of the toxin centripetally emphasises the importance of introducing antitoxin among the central neurons of persons stricken with tetanus. Abbe remarks that he has found in human cases that the intracerebral injection of antitoxin produced prompt arrest of the general convulsive spasm, a remark which I can confirm from a case in which I personally assisted Mr. D'Arcy Power in this operation.

Abbe gives the following directions for introducing the antitoxin intracerebrally. A line is drawn from one auditory meatus to the other across the vertex of the skull. From the point at which this meets the middle line a second line is drawn to the outer angle of the orbit. The middle point of this last line gives the site for the injection (Roux's point). An incision is made in the scalp and a small trephine or drill is used. The operation can be done under a local anæsthetic, but, as Bosanquet and Eyre say in their book, there does not seem to be any advantage in this over general anæsthesia, which also has the advantage of controlling the spasm. The point of the needle is thrust through the dura mater and into the cerebral substance. The antitoxin is then slowly forced into the brain. It is enough to put 5 c.c. into each side. It would seem better to inject the antitoxin into the actual brain substance than into the lateral ventricle, since the latter is practically equivalent to subarachnoid injection, which can be more easily effected by introducing the antitoxin intrathecally. This might be done at the same operation after withdrawing an amount of cerebro-spinal fluid equal to that of the serum injected.

While the above procedure would seem to offer most hope in the case of a person suffering from traumatic tetanus, especially in those cases where the incubation period is short and the disease therefore severe, it would appear rational to introduce the antitoxin at the same time into the circulation, and also locally so as to neutralise any free toxin in these situations. This is desirable also because in some fatal cases of tetanus the bacillus undergoes a certain amount of dissemination. There are advocates, too, of the intraneural injection of antitoxin, but while this is clearly indicated in cases of local tetanus and in ascending tetanus, the intraneural injection does not seem likely to be so valuable as the intracerebral when such phenomena as trismus or rigidity of the neck muscles have appeared; for symptoms such as these imply that the toxin has already reached the higher levels of the central nervous system.

The question as to how to deal with the anaerobic bacillus of Welch when it is also present has not yet been satisfactorily solved. At the present time the best thing to do seems to be to give the wound as much drainage, free air, and permanganate as possible. The announcement of Rosenthal[1] that he has found the serum of an animal prepared against B. perfringens to possess marked preventive properties justifies the hope that before long such a serum may be available for administration in that way.

ARMY AND NAVY MALE NURSES' CO-OPERATION.—The seventh annual general meeting will be held at 89, Harley-street, London, W., on Wednesday next, Nov. 4th, at 3 P.M. H.R.H. Princess Henry of Battenberg will be present to represent Her Majesty Queen Alexandra.

FURTHER RESULTS IN THE ELECTROLYSIS TREATMENT OF CYSTITIS.

BY CHARLES RUSS, M.B. LOND., M.R.C.S. ENG., L.R.C.P. LOND.

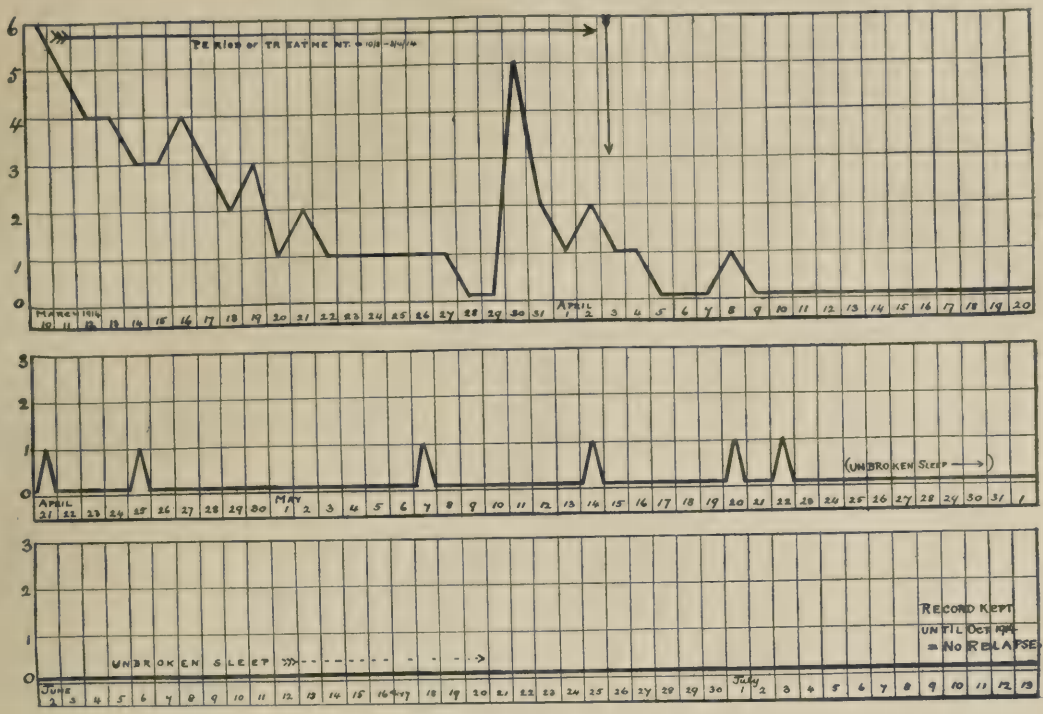
IN THE LANCET of Feb. 14th, 1914, I outlined a new method of treating coli-cystitis. In that article my experimental laboratory work was recalled, and the reasons were shown which led to the evolution of the process. I do not propose to enter into the diagnosis, bacteriology, or prognosis of the malady, for these are adequately dealt with in the text-books; but I intend to set forth the results obtained in some of my recent cases. Since passing the experimental stage I have in the last few years chiefly treated cases of chronic cystitis, and the majority of the patients, whether private or hospital cases, had previously received treatment by vaccine, injections, or lavage.

In a typical case of cystitis one realises that the patient does not much mind any symptom except the frequency. This is really their trouble. The patient's day is disturbed by the frequent or incessant call for micturition, and at night perhaps every hour or two there is a disturbance of sleep. There is little wonder that the victims of the chronic form present the appearance they do, and that their general health becomes undermined. It is usually conceded that the medicinal and other remedies in common use can do little, at least permanently, to combat the frequency. This is necessarily so because of their incapacity to deal directly with the bacteria. My method has the advantage of overcoming the organisms by a succession of blows at them *in situ*, and perhaps this accounts for its success.

The method.—Without going into detail I may repeat its essential points. After the urine is voided a special catheter is passed into the bladder, but no lavage is undertaken. A few ounces of fluid are then passed in, and the catheter with a glass tube attached is fixed upright by a clamp; this makes a fluid system of the bladder, the catheter, and the tubing. The upper level of the fluid is seen through the glass tubing to rise and fall with respiration. A lint-covered metallic belt encircles the lower trunk at the hip level and is connected to one wire of the battery. The other wire (platinum) is passed down the catheter and conveys the current through the fluid to the interior of the bladder. Radiating from the perforations around the catheter eye numerous electric streams pass in all directions through the bladder and lower trunk to reach the metallic core of the belt. In this way we have an electro-chemical action penetrating the bacteria and the entire vesical tissues. This action goes on for an hour or an hour and a half at each treatment. While the treatment proceeds the bladder is being gradually distended by the incoming urine and its recesses become exposed to the forces at work. The patients are unaware of the current's flow and recline at their ease, being occupied in reading and often also enjoy a smoke. If any pain or discomfort is felt it is certain that something in the arrangements needs readjustment. The only modification of the process I described is to increase the time up to one and a half hours at each administration.

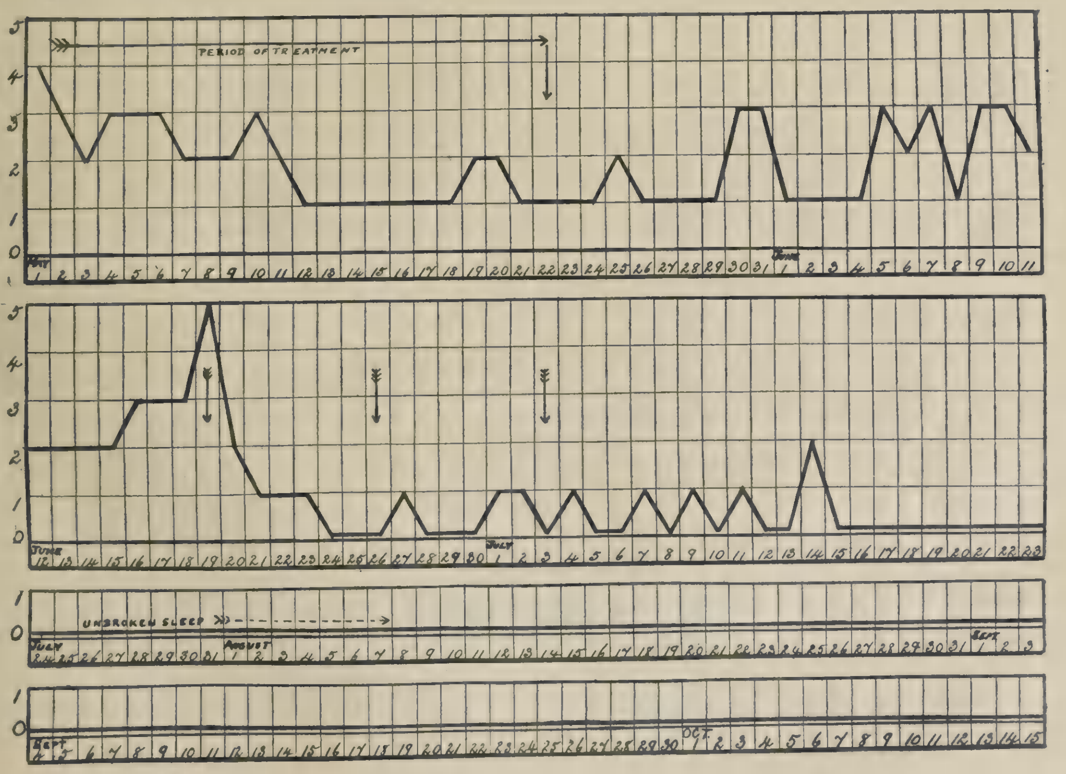
Types of cases illustrated.—I have selected three from my private and hospital cases which show different clinical pictures of cystitis and also

CHART 1.



CASE 1.—Cystitis seven years.

CHART 2.

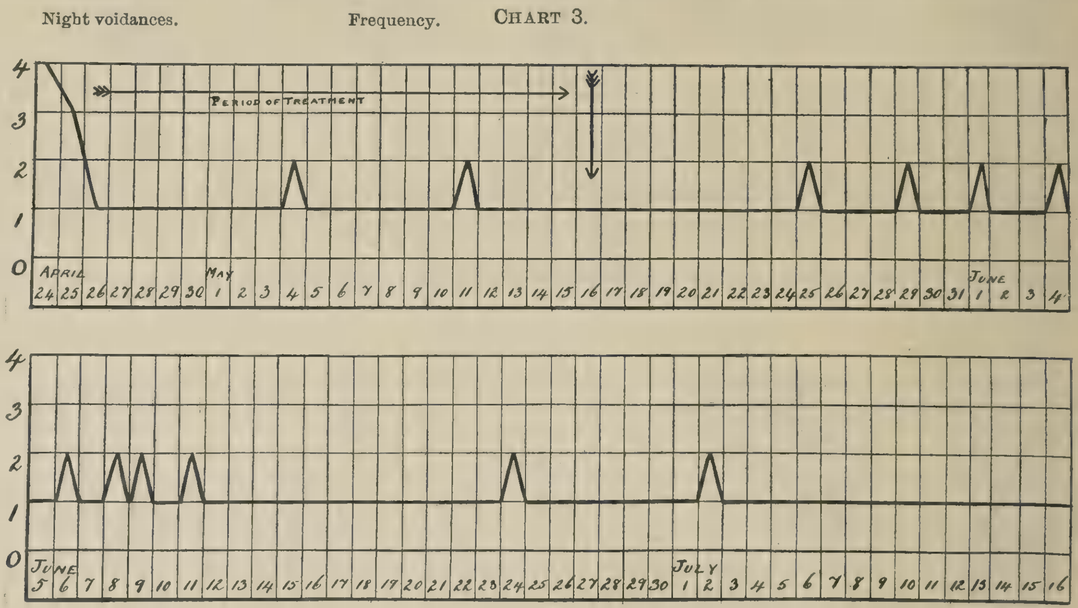


CASE 2.—Cystitis six weeks.

different bacteriology. My method of charting the frequencies is as follows. I take as a standard a night of eight hours' sleep uninterrupted by micturition. The time of voidance when going to bed is the point from which the frequency is calculated. For example, if a patient passes urine before going to bed at 11 P.M., and if there is any further voidance before 7 A.M. the next morning, it is entered in the chart according to the number of voidances within that eight hours. As regards the frequency ascribed to each patient at the commencement of the chart, this is the frequency declared by the patient, and I have only accepted it as a correct average after a careful examination of the history.

CASE 1.—The patient, a man aged 51, attended St. Peter's Hospital for seven years for cystitis. Symptoms: The day frequency equalled one hour, and the night frequency one or two hours. Urine alkaline, containing ropy muco-pus; bacteria (staphylococci) in very large numbers. The patient, who is an abstainer, was pale and depressed by his disorder, for which nothing had produced relief. I began the treatment on March 10th and finished on April 3rd, 1914, which is indicated by the arrows in Chart 1. At the end of the course his urine was neutral and occasionally acid; it contained a trace of pus and still pretty numerous staphylococci. The latter had, however, lost their power to irritate the bladder, and both the pus and staphylococci slowly diminished during observation. Two loopfuls of his urine planted at his visit in September gave only five colonies of the staphylococci. Considering that he had not had a night's sleep for years his recovery was a great relief after so considerable an endurance. When I last saw him he had not had a broken night's rest for over four months. During this patient's course of treatment the current did not exceed three milliampères.

CHART 3.



CASE 3.—Post-prostatectomy cystitis.

CASE 2.—The patient, a man aged 50, had had cystitis for about six weeks. Its onset was ascribed to the passage of a bougie down the urethra. He had passed this instrument himself for 20 years after medical advice of an impending stricture. Frequency equalled one hour by day and four times at night. Urine acid, and contained pus to about one-sixth of its volume; bacteria—staphylococci and colon bacilli. The patient was flushed, anxious, and miserable. His symptoms soon subsided under the treatment, but in view of the tendency to relapse I gave three more separate administrations at intervals of a week. These are shown by the arrows in Chart 2. The patient had residual urine varying from 3 to 8 ounces, and a resistance to the catheter was always met in the deep urethra, suggesting prostatic trouble. Mr. J. G. Pardoe's examination, however, showed an uncommon curve in the deep urethra with a normal prostate. This finding was amply justified by the result of the treatment, for the patient recovered completely. His pus disappeared, and I watched the urine clearing until it was almost a normal specimen. The loss of frequency is seen in the chart to have been established for several months.

CASE 3.—The patient, aged 63, had had cystitis for about two years prior to prostatectomy in March, 1914. The operation had removed the obstruction to micturition, but the pyuria and frequency remained. The urine contained masses of ropy muco-pus; bacteria—proteus bacilli and staphylococci. Frequency equalled four times nightly and about two-hourly by day. The patient was a nervous man suffering from asthma and bronchitis. He soon showed improvement, and up to the end of my charted observations his frequency was reduced to one voidance nightly. (Chart 3.) Perhaps this retentive power is as much as the new anatomy of the organs will permit.

Comment on the results obtained.—The dominant feature is, I think, the diminution and disappearance of the pus from the urine, and this follows the destructive action of the treatment upon the bacteria. The latter cause progressively less inflammation, and this accounts for the reduced frequency. The quantity of pus has been measured by sedimentation of the urine in graduated glasses, and a mixed sample of the night and morning urine is a better guide than a random sample. In alkaline urine the pus soon becomes ropy and cannot be measured accurately. In such cases I find that a few grains of boric acid taken by the mouth four-hourly reduces the alkalinity sufficiently to keep the pus fluid, and comparisons can then be made. Cystitis cases often pass several ounces of pus a day in their urine, and this loss amounts in a week to the impressive quantities which are often evacuated from empyemata. By arrest of this suppuration the drain upon the blood stream is stayed, and the patient's health and strength also become fortified by the longer periods of unbroken sleep.

Permanence of the results.—This important matter can only be proved by continued observation and obtaining the patients' records long after the treatment has ceased. I have been able to secure such records for periods of six months and even a year after giving the treatment, and all my charts are compiled from the patients' manuscript frequency dockets.

Pathological observations and considerations.—1. Large numbers of the bacteria remaining in the bladder after voidance of urine are killed during the flow of the current. They are, however, not all killed during one treatment, but they receive a series of lethal and sublethal electrical penetrations. The bacilli become changed in form and in their staining characters, and finally the urine becomes clear. 2. Observation of stained films from the urinary deposit shows the advent of phagocytosis, sometimes very pronounced, and this is not a common feature in the urine of cystitis. This ingestion of the bacteria by the pus cells of the urine suggests that the treatment induces a congestion of the bladder vessels, which by increasing the opsonin would account for the phagocytosis. I have seen the vessels of varicose ulcers strongly congested after electrolysing them, and if such congestion is induced in the bladder vessels the effect is similar to that of Bier's bandage applied to the limbs. Believing as I do that the opsonin is increased I avoid lavage of the bladder.

I am much indebted to Mr. Pardoe for his interest and support in the development of this method of treatment. Besides selecting cases at St. Peter's Hospital suitable for the treatment he has seen the patients afterwards and at intervals some months later for witness of the permanence of the cure or relief. My thanks are also due to Dr. R. Miller for his excellent suggestion of charting the numerical records of the frequencies.

Beaumont-street, W.

SMALL-POX, VACCINATION, AND THE NEW VACCINATION LAW IN SIAM.

BY H. CAMPBELL HIGHET, M.D. GLASG., D.P.H.,
PRINCIPAL MEDICAL OFFICER, LOCAL GOVERNMENT, SIAM.

Small-pox in Siam.

THROUGHOUT Siam, as in most other eastern countries which are not yet sufficiently protected by vaccination, small-pox is endemic, and from time to time takes on an epidemic form. Amongst the Siamese the disease has two names, the classic name being "kai dara pit," meaning the fever of a very harmful nature, while the vulgar title is "fi dat," the disease characterised by the eruption of boils all over the body. There are no records which show when small-pox first came to this country. In Bangkok it would seem that there is a fairly regular cycle of epidemicity. Every three or four years the disease becomes epidemic, persists for a few months, and dies down again for another two or three years.

The seasonal incidence of small-pox.—30 per cent. of the cases occur during January and 19 per cent. during December, the coolest months of the year in Bangkok.

The general death-rate from small-pox cannot be given in the absence of any knowledge of the number of cases which recovered, but of 379 cases under observation in the hospital for infectious diseases 211 died, giving a death-rate of 55·9 per cent. During the epidemic of 1911–12 the total deaths from small-pox amounted to 2368, equal to a mortality of 4·3 per 1000 of the population, amounting to 540,679 according to the late census (September, 1909).

The age at death in the above cases is given in the accompanying table, which confirms the view that the population of Bangkok is not yet sufficiently protected by vaccination.

Ages at Death from Small-pox.

Age.	Sex.		Total.	Rate. per cent.
	Male.	Female.		
Under 3 months	34	32	66	2·7
3 months to 1 year	277	293	570	24·0
1 to 5 years...	367	349	716	30·2
5 " 10 "	120	125	245	10·3
10 " 20 "	222	132	354	15·0
20 " 25 "	142	64	206	8·7
25 " 35 "	125	48	173	7·3
35 " 45 "	20	[illegible]	26	1·0
45 " 55 "	6	1	7	0·5
55 " 75 "	0	1	1	
Unknown	3	1	4	
—	1316	1052	2368	—

We note then that more than a quarter of these deaths were in infants under one year of age, and that 67·2 per cent. were in children under 10 years of age, a sure indication that vaccination has not been carried out sufficiently in Bangkok.

Methods of prevention against small-pox in Siam.—Vaccination is popular with the Siamese and has been so since its introduction in January, 1840. There are no "conscientious objectors" in Siam, and wherever and whenever a vaccinating officer is at work the people readily submit themselves or their children to vaccination. In the absence of vaccine lymph inoculation is still said to be practised freely in the interior of Siam. The honour of first introducing inoculation and later on vaccination into Siam is due to the American missionaries.

Inoculation against Small-pox in Siam.

As the history of these two movements is of some considerable interest I may be pardoned if I give here a few historical details. In this respect I cannot do better than quote the words of one of the principal actors in the movement, the late Dr. Bradley, the well-known American missionary and editor of the "Bangkok Calendar." In an article entitled "Inoculation for Small-pox," published in the "Bangkok Calendar" of 1865, Dr. Bradley writes as follows:—

> There was once a very extraordinary waking up of the Siamese mind to do something to modify the virulence of small-pox. It took place in the latter part of A.D. 1838. That annual scourge was unusually widespread and malignant at that time. Great efforts had been made by the missionaries every year for the four previous years to introduce vaccination, but all in vain. Being surrounded by the small-pox, with scarcely any hope of shutting it out from their own families, they then felt constrained, by the providence of God, to endeavour to save their children by inoculating them with the small-pox. The blessing of the Lord made it a complete success, every one of the subjects of the experiment having taken the modified small-pox in the mildest form. His late Majesty the King of Siam, being informed of it, sent a body of the royal medical faculty to the missionary physician to inquire into the matter, and then make to him a full report of their investigations. It was a very novel and exciting event for those early years of Prot. Missions, to be visited by such a committee, from such a monarch. Those servants of the king were very particular and thorough in their inquiries, for they had a great charge in hand, and a stern master to serve.

> About that time there was issued, from the press of the A.B.C.F.M. in this city, a little tract in the Siamese language, setting forth the advantages of inoculating for small-pox over having it the natural way, and the wisdom of the former course when the scourge is pressing fearfully upon one, and it is impossible to obtain the vaccine virus. A copy of this was sent to the king, and it was eagerly sought for and read by princes, lords, and the commoners. Presently 10 or 12 royal physicians were ordered by the king to visit the missionary physician daily for the purpose of seeing his practice in inoculating and treating the small-pox thus modified and divested of its virulence, and in this way to qualify themselves for inoculating in the royal palace. Having faithfully studied the art a few days with praiseworthy proficiency, they were armed with lancets and required to inoculate all that were unprotected in the palace of the king, and in the palaces of the princes, and in the families of the nobles and lords, and other officers of government in the city and out of the city. Other native doctors were encouraged by the king to follow this royal example, who extended the work, it is believed, into many of the provinces of Siam.
>
> Inoculation was then the engrossing business and care, not only of nearly all the native physicians, but also of a large proportion of the better classes of the people, from the beginning of the year 1839 until the month of April. It is impossible to estimate the many thousands that were within that period inoculated; and it is very remarkable that amongst them all there was not, probably, more than one case in 500 that proved fatal until the hot season was ushered in, when the work became so much less successful that it was suspended.
>
> The king then evinced his high appreciation of the blessings of inoculation by presenting to each of the royal physicians who had laboured in the work a purse of silver varying from 800 to 400 ticals, and to the missionary physician a purse of 240 ticals.
>
> So generally was inoculation accounted a perfect success that those who had been waked up and blessed by it wished for nothing better to take its place; and consequently it became subsequently an obstacle to the introduction of vaccination, because it was regarded almost as safe and always a more certain protection against small-pox in the natural way than vaccination.

Inoculation was not without its dangers, however, and when vaccination came into vogue inoculation was abandoned for a safe method of prevention.

Vaccination in Siam.

As has been already seen, the introduction of vaccination had been attempted for several years previous to the adoption of inoculation, but it was not until the middle of January, 1840, that the first active vaccine scabs were brought to Siam by an American missionary from Boston, U.S.A., *viâ* the Cape of Good Hope. On the arrival of the vaccine scabs great difficulty was experienced in obtaining subjects for vaccination, but fortunately the then Prime Minister, Somdej Ong Yai, came to the rescue. He placed 75 children at the disposal of the missionaries, and out of a total of 450 insertions three or four good pustules were found on the sixth day. From these vaccine was propagated, and over a hundred persons were vaccinated, but at the end of three months the virus lost its efficiency. To quote again:—

> Vaccination was resuscitated August, 1844, from scabs which were sent from Boston, U.S., overland, being enveloped in a little beeswax. It was propagated with unusual energy and thoroughness by the mission of the A.B.C.F.M. from that time onward for a period of about ten months, when the work was again stopped for the want of fresh virus from the pustules of living subjects. About 1300 persons were thoroughly vaccinated during that period out of about 2000 subjects experimented upon.
>
> After an interval of a year or more the blessing was again brought back through the influence of an American friend sending the virus overland as before; and thus it came and departed, with intervals varying from one year to two, until Dr. Campbell, R.N., F.R.G.S.L., in giving to it more thorough attention at all times for a period of five or six years, has kept it with us much the greater part of the time, and has done great good by it. It is now a settled blessing, not only to the families of all European and American residents of Bangkok, but also to the Siamese in general, among whom it is slowly winning, week by week, a wider range of confidence and usefulness.

It was not until the year 1904 that the Siamese Government undertook the preparation of calf lymph in Bangkok. A vaccine laboratory was then opened at Si Kak Phya Sri by the Hospital Department and large quantities of calf lymph were supplied to the public. It was soon found that more commodious premises were required, and a serum and vaccine laboratory was installed at Phrapratom and work was commenced there in August, 1906 (Siamese era 125). During the year 1912 the Vaccine Laboratory was merged in the Pasteur Institute under the immediate supervision of Dr. Manaud and Dr. Robert, both of whom have been trained in the Pasteur Institute at Paris. During the past seven years 1,890,596 doses of vaccine lymph have been issued to the public, and still small-pox continues to levy a heavy toll upon the population, and more èspecially upon the infants of Siam. It has long been evident, therefore, that the present voluntary system of vaccination is quite inadequate as a protection against epidemics of small-pox, but before a law for compulsory vaccination could be enacted certain necessary preliminary steps had to be taken.

The establishment of a vaccine laboratory was *the first step*, and, as we have already seen, this has been an unqualified success. *The second step* was the training of a sufficient number of vaccinators. For several years past suitable young men have undergone a course of instruction with regard to small-pox, the effects of vaccination, and the methods of vaccination. These have been examined by myself or my deputy, and certificates have been granted only to those who have shown reasonable proficiency and knowledge. In addition to these, all our sanitary inspectors are trained in the art of vaccination.

A third step was to accustom the public to regular vaccination every year. In order to carry this out a beginning was made seven years ago in Bangkok. Temporary vaccination stations were established by the Local Sanitary Department in hospitals, temples, and police stations throughout the city. These were kept open during the cooler months of the year, which is the season most preferred by the Siamese for vaccination. On the first occasion 3620 vaccinations were performed. Every year since then free vaccination has been provided, not only in Bangkok, but also in the outlying suburbs and in the muangs of the Bangkok monthon. During the past seven years a total of 80,934 vaccinations have been performed by officers of the Local Sanitary Department alone.

In the other monthons of Siam—those under the Ministry of Interior—vaccination has also been carried out on a large scale. During the past 12 months a special vaccination campaign has been carried out in the interior at the instigation of His Majesty the King, who has most generously defrayed all the expenses out of His Majesty's own purse. Up to April 13th of this year this special campaign has resulted in 304,938 vaccinations during the 12 months.

So far, then, as the present generation is concerned, it may be said that a large portion of the population of Siam is for the present fairly well protected against small-pox. People in the distant parts of the interior who never heard of vaccination before will now be able to judge of its value when the next case of small-pox develops in their midst. They are now accustomed to the operation and to the appearance of vaccinating officers in their district, so that the country may be now considered to be ready for the final step to which we have looked forward so long—i.e., a compulsory vaccination Act.

The Vaccination Law of B.E. 2456.

On Feb. 19th of this year B.E. 2456 (1914) His Majesty was graciously pleased to sanction the enactment of a vaccination law for Siam. The law was drafted by the Local Sanitary Department for application in the Bangkok province, and was revised by His Royal Highness Krom Phra Damrong, Minister of Interior, so that it is now applicable to the whole of Siam. At present it will only apply to the monthon of Bangkok, but at any time it may be proclaimed for other monthons in the interior.

A few words may now be said with regard to the chief provisions of this law. The basal idea is the desire to have every person now in the kingdom or who may enter the kingdom rendered immune to small-pox. Therefore as soon as this law comes into force every person who has not previously been successfully vaccinated must become vaccinated, unless it can be shown by a certificate from a duly qualified public vaccinator that he or she is immune to vaccination. Immunity may mean that he or she has previously suffered from small-pox or has been repeatedly vaccinated without a successful result.

Every parent or guardian of a child over one month old must take the earliest opportunity of having such child vaccinated. No definite time limit is laid down in the law, as, for example, during the first three, six, or 12 months after birth, owing to the many difficulties which might be experienced under local conditions. It will be left to the superintendent of vaccination to make such arrangements as are necessary from time to time, and to notify the time and place for vaccinations in any district. This will enable us to commence work during the cooler months of the year when vaccination is more popular in Siam. The origin of this preference is doubtless due to the fact that it was only in cool weather that vaccine lymph could be transported any appreciable distance when transport was slow and difficult. Nowadays, with railway communication, ice and thermos flasks, efficient vaccine lymph can be transported to almost every corner of the country at any time during the year.

Another point of importance in the law is the provision that the vaccinated child must be brought back to the vaccinator on the eighth day after vaccination so that the result may be verified. This will enable us to repeat the vaccination when necessary, and to check the efficiency of the lymph and the capabilities of the vaccinator. Certificates showing the result of vaccination will be granted. We look forward to the day when no child will be admitted as a scholar into any school whatever unless he can show a certificate of vaccination or of immunity from small-pox.

One of the most important clauses in the law is Clause IX. This gives the Minister power to issue a public notice enforcing vaccination or revaccination upon all the inhabitants of a district or locality within a specified time. Such power would only be taken in the possibility of small-pox becoming epidemic in such district or locality. No definite age is prescribed by this law for revaccination, but it is hoped that an addition will be made to it, definitely laying down that revaccination during the ninth year will be compulsory. The usual clauses permitting of postponement of vaccination in case of sickness of the child are included in the law.

Public vaccination will be performed free of charge at such times and places as may be notified by the superintendent of vaccination. Any person may, however, apply to a public vaccinator to perform vaccination at his residence, and in such case if the public vaccinator is employed by the Government a fee will be charged at a rate prescribed by the Minister. No restrictions are placed upon private medical practitioners as to time and place of vaccination and the fees to be charged. They will, however, require to take out licences as public vaccinators, if they wish to have their certificates recognised, for in accordance with Clause XI. the certificate of a public vaccinator shall be the legal proof of being vaccinated in accordance with the provision of the law. The reason for this is the necessity of protecting the public. No unqualified person will be recognised as a public vaccinator, and the lymph to be used must only be that which has been authorised by the Minister. The dangerous practice of inoculating with small-pox virus is now declared to be a criminal offence, and the offender will be liable to heavy penalties.

In conclusion, it may be stated that the "conscientious objector" has not been recognised in this law.

Bangkok.

PERIOSTEAL WHITLOW.

BY HUGHES R. DAVIES, M.R.C.S. ENG., L.R.C.P. LOND.,
PHYSICIAN TO THE SPANISH AND PORTUGUESE JEWS' HOSPITAL, MILE-END, E.

THE literature upon this subject appears to be scanty and unsatisfactory, and, with one exception available, that of the late H. W. Allingham, I find little that bears intimately upon the particular case I now record. From a paper read before the St. George's Hospital Hunterian Society and afterwards published[1] I make the following important excerpts, and desire to draw special attention, by italics, to the sound deduction of that lamented and brilliant surgeon, which the case I now bring before the profession amply verifies.

> "The last phalanx has no real periosteum. its deficiency being supplied by the cellular tissue covering it."

And then his theory that—

> "There being no periosteum to the bone its place is supplied by the soft tissues of the finger; consequently when an inflammation attacks the tissues it strangulates the vessels running in it to the bone, and so cuts off the blood-supply, and as a result of such a proceeding causes the phalanx to necrose. ...... It is well known in cases of necrosis that the new bone is formed from what remains of the periosteum, fascia, tendons, and whatever was near the original bone. *I therefore cannot see why new bone should not be formed from the cellular tissue surrounding the cavity from whence the phalanx is removed, and of course helped by the remaining epiphysis.*"

He remarks that:—

> "The flexor profundus is attached to the proximal end (the epiphysis) of the terminal phalanx, the sheaths of which blend with the periosteum."

This epiphysis, Allingham declared, always remained behind after necrosis of the terminal phalanx.

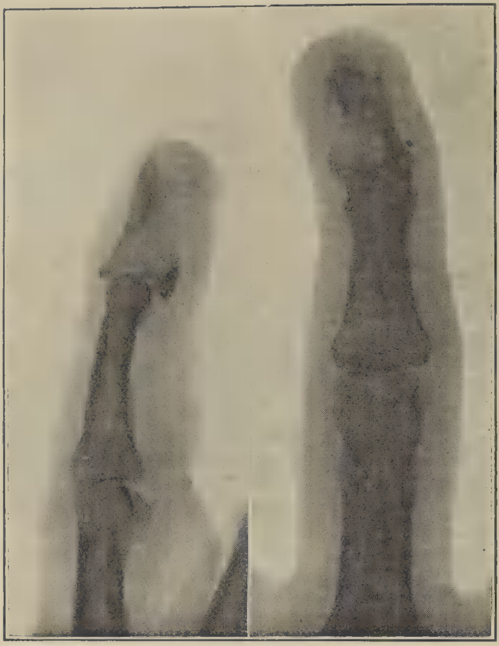
---

[1] Medical Press, Sept. 29th, 1886.

With this short introduction I will now record my interesting experience.

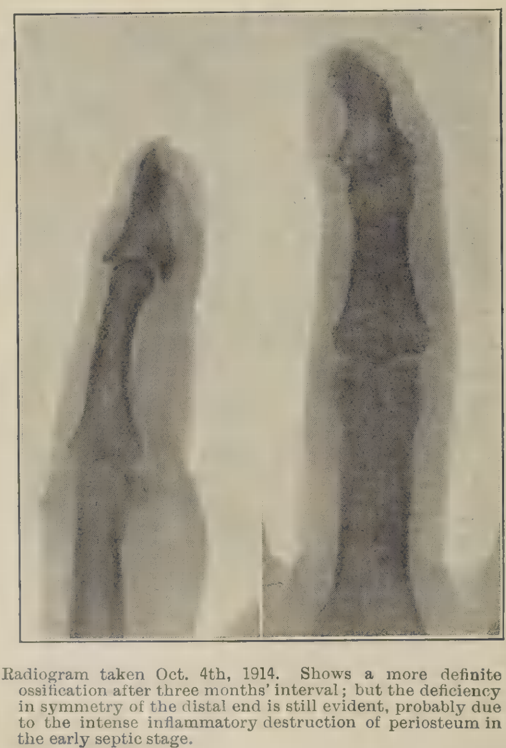
On Feb. 6th, 1914, I was consulted by a man, aged 57 years, on account of a whitlow on the terminal phalanx of the second finger of the right hand. The patient was in a very low state of health generally, and there was tenderness in the axilla, together with marked enlargement of the cubital gland. A bootmaker by trade, it is quite possible that the examining finger may have been wounded by a septic nail in the sole of a boot, and his ill-health have been a contributory cause of the trouble. I incised the centre of suppuration at once, and advised constant boracic fomentation. Within a few hours the condition of the finger was deplorable on account of numerous discharging sinuses which appeared all over the terminal phalanx. These sinuses I broke down immediately, making one general exit for the pus. A probe revealed exposed bone, and the finger nail seemed fated; indeed, as the inflammatory condition spread rapidly towards the hand I was much tempted to advise amputation of the offending phalanx. Fortunately, I refrained, and continued expectant treatment; but the discharge was profuse and lasting.

FIG. 1.



Radiogram taken July 4th, 1914. Shows the asymmetrical condition of the distal end of phalanx as well as the immaturity of the ossification of the new bone at the base of the phalanx.

FIG. 2.

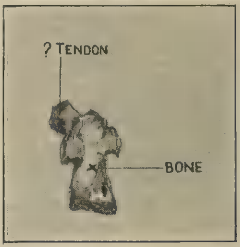


Radiogram taken Oct. 4th, 1914. Shows a more definite ossification after three months' interval; but the deficiency in symmetry of the distal end is still evident, probably due to the intense inflammatory destruction of periosteum in the early septic stage.

On March 2nd, the discharge still continuing, I passed a pair of forceps and gripped the terminal phalanx, which came away easily, bearing evidence of ligamentous and tendinous attachments. Again the question arose as to the advisability of amputation. But as the nail was rehabilitating itself so wonderfully well, stiffening the terminal joint, and as the swelling of the second phalanx showed evidence of subsiding, I again refrained from operating. However, the sinus and the discharge persisting, I was compelled to believe that there still existed some bone necrosis—or that all had not come away.

On May 8th this fear proved actual fact, for two small portions of necrosed phalanx came through the sinus, which then happily closed, leaving a satisfactory finger for use. It was then that I noticed that a surprising stiffening of the flaccid phalanx was commencing, principally at the base, and a radiograph on July 4th revealed the presence of a perfectly new phalanx. The upper portion of the negative plainly showed a deficiency in the symmetry of the new growth—probably the site of the recently ejected pieces of bone, which had prevented an earlier closing of the sinus by reason of their presence.

FIG. 3.



Sketch of necrosed phalanx removed by forceps March 2nd, 1914. In this instance apparently, in the removed necrosed phalanx, the tendon of the flexor profundus has attachment to the distal end of the phalanx, and not to the epiphysis as asserted by Allingham.

I take it that the necrosed original phalanx must have shelled out from the periosteum when seized by my forceps on March 2nd, since which date time, and hopeful patience, accomplished an apparent miracle—or the unexpected.

I present a sketch of the removed necrosed phalanx (or, according to Allingham, the phalanx *minus* the epiphyseal end), actual size, and the two radiographs, taken at the interval of exactly three months. They are worthy of study.

I venture to hope that this record will be valuable as showing what nature, guided, can perform; and also as a warning that a too-hurried use of the scalpel is not always desirable. During the course of treatment Allingham suggested that the nail, after the necrosed bone has been removed, should be strapped back to a small dorsal splint, to militate against an unsightly curving of the nail before the new phalanx has grown. In theory this sounds well, but in actual practice, as in my case, it would scarcely be feasible, since the slightest rough treatment would have torn the dead nail at once from its bed, and the flaccid terminal would have lost a certain temporary support. Besides, the strapping would have interfered with the frequent and necessary dressing of the sinus.

SECTION OF DERMATOLOGY.

Exhibition of Cases.

A meeting of this section was held on Oct. 15th. Before opening the proceedings, Dr. J. J. Pringle, the President, announced that the meetings of the section would be held as usual during the forthcoming session.

The President showed a Lichenous Eruption in a woman 57 years of age. The lesions, which occupied large areas of the body and limbs, consisted of papules of both plane and acuminate type. He questioned as to whether the case was one of pityriasis rubra pilaris or of lichen planus, or whether it was possibly a combination of the two conditions due to some common underlying cause.—Dr. J. H. Sequeira had seen a similar case.—Dr. H. G. Adamson and Dr. J. M. H. MacLeod were in favour of the diagnosis of pityriasis rubra pilaris, towards which the President leaned.

Dr. W. Knowsley Sibley brought up a boy whom he had shown at a previous meeting on account of a peculiar generalised nodular eruption; the lesions had increased in size and number and the blood now showed the characteristic changes of lymphatic leukæmia.

Dr. Graham Little showed (1) a case of (?) Infective Granuloma occurring on the site of an old pigmentary nævus and (2) a case of Lichen Planus.

Dr. Sequeira showed: 1. A patient with an indurated, slowly growing Nodule on the chin for which he suggested the diagnosis of sarcoid, and in this the President concurred. 2. A case of Myxo-sarcoma of the skin of the forehead and face in a patient who had had an amputation of the foot four years previously for chondro-sarcoma of the tarsus.

Mr. H. C. Samuel brought up a patient with Symmetrical Pigmentation, Atrophy, and Telangiectases of the skin of the beard region resembling an X ray burn, but with absence of a history of exposure to X rays. He suggested a diagnosis of xerodermia pigmentosa commencing in an adult.—In the discussion which followed several speakers expressed the view that the patient was deliberately withholding the history of exposure to X rays.

Dr. S. E. Dore showed a case of Multiple Soft Fibromata.

Dr. Adamson brought a patient with peculiar Nodular Lesions about the face which gave it the leonine appearance of leprosy; there was, in addition, definite thickening of the bones of the nose. Dr. Adamson thought that the nodules might be analogous to rheumatic nodules.—The President stated that the case reminded him of erythema diutinum, while Dr. F. Parkes Weber thought it a form of leontiasis ossium.

Dr. Adamson also showed an atypical form of Lupus Vulgaris on the Thigh, the diagnosis of which from ulcerating syphilide had been extremely difficult.

Dr. George Pernet demonstrated cultures of Favus and Ringworm.

Dr. H. MacCormac showed a case with Lichen Spinulosus-like Lesions which on the face gave rise to atrophic patches like lupus erythematosus; he thought it was a tuberculide.—Dr. Adamson agreed as to its nature.—Dr. Morelle (Brussels) had also seen a somewhat similar case.

Mr. P. P. Atal (for Mr. Charles Gibbs) showed an extensive case of Keratodermia Blennorrhagica.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Restraint in Mental Disease.

The autumn meeting of the Midland and Northern Division of this association was held by invitation of Dr. Graeme Dickson at Wye House, Buxton, on Oct. 22nd. Dr. Dickson presided.

Dr. R. C. Stewart read a short paper on Restraint in Mental Disease with the object of opening up a discussion on this subject. He dealt with restraint in its widest sense, and considered briefly mechanical restraint, the use of single rooms, the question of locked doors in asylums, treatment by sedatives, &c. He was of opinion that everything that took away the feeling of restraint tended to benefit the patient.

The paper was followed by an interesting discussion, in which every member present took part, and various opinions were expressed on the numerous points raised. One speaker held very strong opinions about mechanical restraint, and thought it ought never to be used, or only in very rare cases. He considered it had a bad moral effect on the nursing staff. Seclusion appeared to him only a lesser evil, and he did not like using drugs. It had always been a difficult problem with him to decide what was the best treatment for perverse old chronic patients. A distinction was drawn between acute and chronic cases, and it was generally agreed that the difficulty of finding a suitable means of restraint lay in the case of the latter. The use of verandahs and sleeping out of doors for noisy patients were considered beneficial. The various forms of sedatives in use were referred to, and special reference was made to the use of bromides. The limitation of airing courts by unclimbable fencing and the old question of the locked asylum door were to some extent dealt with. It was suggested that too many single rooms were provided in many asylums, and that they might be better used as "privilege" rooms than for the isolation of noisy patients.

Dr. Stewart replied, after which a hearty vote of thanks was accorded to Dr. Dickson for his kind hospitality.

Æsculapian Society.—A meeting of this society was held on Oct. 23rd, Dr. David Ross, a past President, being in the chair.—Mr. Wallace C. G. Ashdowne showed: 1. A man, aged 37, admitted for treatment of femoral hernia, who showed marked signs of Acromegaly, giantism, sexual undevelopment, and prominent lower jaw being well marked. 2. A man, aged 47, with a Tumour in the left side of the pelvis, extending to the inguinal region and round to the perineum, and it could be traced through the obturator foramen. A second tumour could be felt higher up in the position of the descending colon. Some occult blood was found, and since admission 2 or 3 ounces of bright, pure blood were passed. Operation was deemed out of the question on account of the extent of the tumour. 3. A man, aged 60, who had his penis removed for Epithelioma of glans. The penis was entirely removed and the mucous membrane attached to the skin in the perineum. The man was able to micturate in comfort by means of a funnel-shaped aluminium instrument devised by himself. Spinal anæsthesia was used for the operation, as the man had aortic aneurysm. 4. A man suffering from Tertiary Syphilitic Ulceration of the Pharynx, who had one injection of neosalvarsan in addition to mercury and potassium iodide. He was improving. 5. A young man, aged 19, who injured his left hip ten years ago through a fall from a swing. No inconvenience followed for three weeks, when pain occurred on walking. Tuberculous disease of the hip was suspected and extension applied for 18 months; extension had again been used more recently. On admission to the Metropolitan Hospital it was found that the head of the femur was dislocated upwards and forwards and the leg shortened ⅝ inch. The patient could walk up to three miles without pain. It was thought unnecessary to interfere. 6. A skiagram demonstrating Stones in Gall-bladder. 7. A Stone about 2 inches in length and ¾ inch in diameter found post mortem in the cystic duct of a woman who died from chronic bronchitis aged 88. The gall-bladder was quite free and there were no symptoms during life. 8. A boy, aged

6 years, from whose right ureter a calculus measuring 1 inch by ⅜ inch was removed. The calculus did not obstruct the passage of water, having formed a cul-de-sac. A second stone was removed later and gravel was still being passed.

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held on Oct. 20th at St. John's Hospital for Diseases of the Skin, Dr. J. L. Bunch being in the chair. —Dr. Bunch showed: 1. A case of Seborrhœic Dermatitis in a patient who had suffered from syphilis; the lesions showed induration, and were situated on the forehead and both auricles. 2. A case of Tertiary Syphilis in a woman; the lesions of an indurated type were present on the legs and arms, and were deeply pigmented. 3. A case of Lipomatous Tumour of the Scalp in a man aged 55; the condition had been present for 23 years, and was said to have resulted from a kick. 4. A case of Cheiro-Pompholyx in a girl aged 14; the vesicles were present on the dorsum and palms of both hands.—Dr. H. W. Barber showed a case of Abnormal Syphilide in a boy; the lesion took the form of a swelling in the left groin with an infiltration of the surrounding skin over which was distributed a vesicular eruption; there was a generalised glandular enlargement, but the Wassermann reaction was negative; the microscopic section was that of a granuloma with formation of vesicles.—Mr. T. Wilson showed a case of Scleroderma of symmetrical distribution in a woman aged 45.—Dr. Morgan Dockrell showed a case of Multiple Idiopathic Pigmentary Sarcoma in a man, aged 50, who had been having a streptococcal vaccine with good results.—Dr. Simonds Gooding showed a case of Verruca Necrogenica in a man, aged 30, who worked in a cold storage. The lesions were situated on the angle of the jaw. Also an unusual case of Pigmentation of the Skin extending from the patellæ down to the feet of three months' duration in a man who some years previously had suffered from syphilis.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The annual meeting of this society was held on Oct. 19th. The attendance was, of course, unusually small, as many members are absent on naval and military service. On the recommendation of the new President, Dr. W. H. C. Newnham, it was decided to send a message of greeting to all these absentees. The Presidential address dealt in a most interesting way with the birth and growth of gynæcology and with some of the more important aspects of that subject at the present time. Dr. Newnham laid special stress on the importance of gonorrhœa in women as a cause of invalidism and sterility. The annual report was read by Dr. J. A. Nixon—the actual secretary, Mr. A. J. M. Wright, being absent on duty with the Territorial army. The financial position of the society is unfortunately not very reassuring, but there is reason to believe that means will be found for overcoming the chief difficulties. It is, of course, impossible to make any radical alterations at the present time.

EXETER CITY ASYLUM.—At the last meeting of the Exeter city council it was decided to advertise for a medical superintendent for the asylum at a salary of £500, increasing to £600, per annum. It was proposed that the officer devote the whole of his time to the work and should not engage in any outside practice, including consultative work. This was opposed on the ground that it would be beneficial to have a mental specialist for the assistance of private medical practitioners. After a considerable discussion the proposition was carried by a large majority.

ROENTGEN SOCIETY.—A general meeting of this society will be held on Tuesday next, Nov. 3rd, at 8.15 P.M., at the Institution of Electrical Engineers, Victoria Embankment, W.C., when the President, Sir Alfred Pearce Gould, K.C.V.O., will deliver his presidential address. Members desirous of reading papers, showing new apparatus, negatives, or lantern slides are requested to communicate with the honorary secretary, Dr. Robert Knox, 7, Harley-street, W.

Reviews and Notices of Books.

Pain: its Origin, Conduction, Perception, and Diagnostic Significance.

By RICHARD J. BEHAN, M.D., formerly Associate Professor of Physical Diagnosis, Western Pennsylvania Medical College, &c. With 191 illustrations in the text and many diagnostic charts. London and New York: D. Appleton and Co. 1914. Pp. 920. Price 25s. net.

WE suppose that pain is a symptom more frequently complained of by a patient and more certain to lead him to consult a physician than any other that might be mentioned. Essentially subjective as it is, moreover, unless it reveals itself by unmistakable outward expression the physician is not in a position either to affirm or deny its reality. The phrase "imaginary pain" is meaningless; if a patient honestly believes he is suffering pain, he is suffering pain; and when the patient says the pain is gone, it is gone. Unless the physician is well versed in the interpretation of pain phenomena the subjective nature of the symptom of itself will not give him much aid. He must know the various causes of a given pain, the reasons for its appearance in the particular case, and the different diseases giving rise to pain of similar character and localisation ere he can determine its exact significance.

Dr. Behan's book is calculated to furnish the practitioner with a valuable aid to the interpretation of pain. The study of the phenomenon involves little less than a survey of the whole field of internal medicine, and we are not surprised that a volume of over 900 pages has been found necessary for an adequate presentation of the subject. After introductory chapters on the nature of pain, its perception, classification, intensity, and distribution, the author proceeds to examine pain as it occurs in the various forms of disease of the nervous system, bones, circulatory system, glands, eye, ear, nose, throat, chest, and so on. To the subject of pain in the abdomen and abdominal organs no fewer than 390 pages are devoted. The systematisation of the work is noteworthy; there is no confusion and but little overlapping, and with the help of an excellent index the reader will find reference to any particular point a matter of ease. There is a bibliography which must contain over 1200 references to the subject and is sure to be of value to the student.

The critical reader will find various opinions expressed to which exception might be taken, but minute criticism cannot be entered into in a brief review. Oddly enough, we can find no reference to meralgia paræsthetica (Bernhardt's disease) either in the text or in the bibliography. Taken as a whole, we do not know of any single volume which contains so much interesting and valuable clinical information on the subject, and which has an appeal as much to the specialist as to the practitioner. We should think that it will be found eminently serviceable in everyday practice.

Cancer Experimental.

Por el Dr. ANGEL H. ROFFO. Buenos Aires: Libreria y Casa Editora de A. Guidi Buffarini. Pp. 319 + xxxiv.

Dr. Roffo gives an account of the present state of our knowledge in regard to the transmissibility of cancer in animals and of his own very extensive experimental work on the subject. The book is divided into six chapters. Chapter I. gives a brief survey of the recent work of Loeb, Reinke, Freund, Askenazi, Ehrlich, Wassermann, and others on cellular biology and pathology. The subject of the action of chemical and physico-chemical irritants, of micro-organisms and fungi, and of their possible rôle in the etiology of cancer is discussed in Chapter II. Dr. Roffo expresses his disbelief in the parasitic theory of cancer, and attaches little importance to the claims of various experimenters either to have isolated any specific cancer-producing micro-organism or to have produced true cancers by any form of injection or inoculation of such micro-organisms. In Chapter III. the author deals with the transplantation of tissues, and goes on to discuss spontaneous cancer in animals and the numerous attempts to engraft human cancer upon animals which have been made by experimenters in many different countries. He does not admit the possibility of such engrafting, and maintains that the latest experimental work demonstrates that for the successful transplantation of malignant neoplasms "normal" conditions are necessary—that is to say, the transplantation must be made on an animal of the same species.

Chapters IV. and V. are devoted to a description of the author's methods and results in the transplantation of cancerous growths and a discussion of the theory of the transmission of cancer from animal to animal by ecto- or endoparasites, a theory of "cancer cages" on all fours with the theory of "cancer houses" which has been a good deal discussed of late. Dr. Roffo has made a considerable number of experiments with a view to testing this theory of the transmission of cancer by infection or contagion. His results have been uniformly negative, and he pronounces as follows in summing up the whole matter: "The only method by which we can transmit cancer in animals is that of transplantation of cancerous tissue in its integrity on animals belonging to the same race and species as that from which the cancerous tissue is taken. Attempts at transmission to animals of the same species made with substances extracted from a cancerous animal or from the tumour itself have been uniformly unsuccessful." The remainder of Chapter V. contains a full account of Dr. Roffo's experimental work on cancer transplantation in white rats and his conclusions concerning the various factors which favour or tend to prevent successful transplantation. He is of opinion that individual white rats may possess a spontaneous immunity to cancer, and quotes the work of Bashford and others showing that a condition of artificial or therapeutic immunity may be brought about in animals by the injection of blood from healthy animals of the same species, of emulsions of various organs, or by the transplantation and absorption of portions of malignant tumours. In each case positive results are only obtained when material from animals of the same species is used for immunising.

In the sixth and concluding chapter recent experimental work on the radio- and chemio-therapy of cancer is very fully described and discussed, especially Wassermann's work with preparations of selenium. Dr. Roffo details a series of experiments made by himself with eosin-selenium to which was added a salt of rubidium. The addition of rubidium admitted of a reduction in the dose of selenium without loss of efficacy, a very desirable object in view of the extreme toxicity of selenium and its preparations. With the eosin-selenium-rubidium he found that it was possible to arrest the development and growth of cancerous tumours in white rats and to bring about their softening and absorption. The solution acts primarily on the nucleus of the cancer cell, causing fragmentation and vacuolisation. If the tumour is small complete reabsorption may take place; if large, the animal dies poisoned by the absorption of cadaveric products.

Dr. Roffo's work is enriched by an immense number of beautifully executed coloured plates and microphotographs, and contains a very full bibliography.

Ernährung und Stoffwechselkrankheiten.

Von Professor Dr. F. UMBER, Dirigierendem Arzt der I. inneren Abteilung des städtischen Krankenhauses, Charlottenburg-Westend, Berlin. Zweite neubearbeitete Auflage, mit 10 Abbildungen, 10 schwarzen und 11 farbigen Tafeln. Berlin und Wien: Urban und Schwarzenberg. 1914. Pp. 513. Price 18 marks.

THE first edition of this treatise appeared in 1909, since which important advances have been made in the study of the metabolism in disease, more especially in relation to lipoids, the relation of internal secretions to many metabolic disturbances, such as obesity and diabetes, and the whole question of the chemistry of colloids.

The introductory chapter on nutrition and nutritive substances gives a succinct account of the requirements of nutrition in general, and a specific account of proteins, carbohydrates, fats, and mineral metabolism on the usual lines. After this, the first subject dealt with is what is to be done with patients who are "under-nourished," those whose nutrition is impaired from one cause or other, including an account of the various forms of so-called cures that are adopted, more especially in Germany. Next artificial feeding—i.e., extrabuccal or parenteric nutrition—is dealt with. This includes an account of feeding by means of a sound or œsophageal tube, rectal alimentation, and the introduction of nutriments either subcutaneously or by intravenous injection. Elaborate tables and formulæ are given of the composition of foods used in these operations. Then follows a concise chapter of about 60 pages on obesity, its causes, symptomatology, and therapeutics, illustrated by several cases that came under the author's care. The chemical aspect of the metabolism in these cases is given in very full detail. Over 250 pages are devoted to the subject of diabetes mellitus. This chapter is, in fact, an admirable monograph on this subject in all its aspects, including temporary and permanent glycosuria, its clinical forms, symptomatology, complications, prognosis, and therapeutics. Here also the author from his own varied experience is able to add much that is both interesting and practical. This chapter is well worthy of the careful attention of clinicians. The cases cited were investigated with a thoroughness that does not obtain in every hospital. A plate is added showing the condition described by von Noorden as xanthosis diabetica. Many valuable suggestions as to the treatment of the "complications" are offered. Next follows an account of the rarer forms of disturbance of carbohydrate metabolism represented by lactosuria, pentosuria—a subject brought home to English clinicians by Dr. A. E. Garrod, fructosuria, and the still rarer heptosuria. Diabetes insipidus, though strictly speaking it does not belong to diseases of metabolism, is next dealt with, and the conclusion is arrived at that treatment is not very successful.

The remarks on gout, which form an exposition of this subject, should be read by clinicians who see much of this disease in its varied and protean forms. The reader must bring to the study of this chapter a fair knowledge of the chemistry of the purins and allied bodies. The work of Dyce Duckworth is frequently referred to, and good illustrations are given of the effects of lead and of Heberden's nodes in chronic articular rheumatism as revealed by the X rays. About 50 pages are given to the formation of calculi in the urinary passages, and the work ends with a short account of what the author calls "amino acid diathesis," including cystinuria, diaminuria, and alkaptonuria.

We can commend this thoroughly scientific and withal practical treatise to the attention of our English clinicians.

A Handbook of Fevers.

By J. CAMPBELL McCLURE, M.D. Glasg. London: Shaw and Sons. 1914. Pp. 470, with 28 temperature charts.

THE author of this useful volume has endeavoured to produce a handbook of fevers for the use of students and general practitioners of medicine, and to make his work before all things practical in character. Detailed descriptions of the pathological anatomy are not included, epidemiology and bacteriology are touched upon with a light hand, but treatment is discussed at full length and with plenty of practical directions. The first chapter gives a brief general account of fever and its management; it is recommended that alcohol should be used, if at all, as a drug, and only to tide over certain emergencies, in quantities of from two to four ounces a day. It is of value, as Dr. McClure points out, as a hypnotic and sedative for children and adults, in addition to being notoriously a diffusible stimulant. As for drugs that reduce the temperature the author says: "It is a good rule never to give antipyretic drugs." Thirteen chapters follow on as many fevers of known bacteriology, then ten on fevers of uncertain bacteriology, scarlet fever, measles, German measles, small-pox, chicken-pox, typhus, mumps, rheumatic fever, yellow fever, and whooping-cough. At the end of the book beri-beri, pellagra, and the treatment of tuberculosis with Mehnarto's contratoxin are considered, and there is a good index.

It is perhaps surprising that no room has been found in the volume for acute anterior poliomyelitis, an endemic fever of which small epidemics have occurred in England during the last few years. The account of epidemic cerebro-spinal meningitis, excellent as it is, would gain by more up-to-date references to the extensive literature of the subject, particularly to that hailing from America. For the rest, we have nothing but praise. The book is well written, comprehensive, and particularly thorough in its description of the management of cases.

LIBRARY TABLE.

A Short History of Germany and Her Colonies. By WALTER ALISON PHILLIPS, JAMES WYCLIFFE HEADLAM, and ARTHUR WILLIAM HOLLAND. Pp. 174. *A Short History of France.* By PAUL WIRIATH and J. E. C. BODLEY. Pp. 224. *Belgium, Italy, and Switzerland.* By the Rev. G. EDMUNDSON, H. WICKHAM STEED, and the Rev. W. A. B. COOLIDGE. Pp. 202. *A Short History of Austria-Hungary and Poland.* By H. WICKHAM STEED, WALTER ALISON PHILLIPS, and DAVID HANNAY. Pp. 170. *A Short History of Russia and the Balkan States.* By Sir DONALD MACKENZIE WALLACE, Prince KROPOTKIN, C. MIJATOVICH, and J. D. BOURCHIER. Pp. 186. *The Wars of the Nineteenth Century.* By Major-General C. W. ROBINSON, C.B., Colonel MAUDE, C. B., Lieutenant-Colonel J. H. VERRINDER CROWE, Captain C. F. ATKINSON, and others. Pp. 260. London: The Encyclopædia Britannica Company, Limited. 1914. Price 2*s.* 6*d.* net each volume.—The above volumes form a series of six handbooks covering the history, physical features, population, communications, industry and commerce, education, government, military and naval resources, and other interesting information concerning the countries that are now almost monopolising the attention of the entire world in consequence of the European war. The volumes consist of the various authoritative articles from the eleventh edition of the "Encyclopædia Britannica," arranged in a uniform sequence in the different volumes so as to form corresponding chapters. The last of the series contains full accounts of the political bearings, the course and results of the French Revolutionary War, the Napoleonic Campaigns, the Peninsular War, the Waterloo Campaign 1815, the Italian Wars 1848-70, the Schleswig-Holstein Question, the Seven Weeks (Austro-Prussian) War 1866, the Franco-German War, the Russo-Turkish War, the Servo-Bulgarian War, the Spanish-American War, the South African War, the Russo-Japanese War, the Turco-Italian War, and the Balkan War of 1912. It was a happy idea to collect into separate handy volumes, at the moderate price of 2*s.* 6*d.* each, or 12*s.* 6*d.* the set of six, all the carefully compiled and accurate information scattered through the pages of the "Encyclopædia Britannica." Photographs embellish the books, and special value will attach to the views of architectural masterpieces and historic shrines hitherto the glory of the civilised world, but now laid in ruins.

Mechano-therapeutics in General Practice. By G. DE SWIETOCHOWSKI, M.D. Munich, M.R.C.S. Eng., Clinical Assistant, Electrical and Massage Department, King's College Hospital. Illustrated. London: H. K. Lewis. 1914. Pp. 141. Price 4*s.* net.—This little book is intended to be a guide to the performance of massage in cases in general practice. It contains a great deal of useful information and sensible advice. There is no doubt that massage is still largely neglected by general practitioners, and that many excellent results could be obtained by its use in suitable cases if medical men would take up this work for themselves and rely less on the masseur. The subject is classified in the usual way into surgical, medical, and special sections, injuries and diseases being taken in regional order. Used with caution and with a knowledge of what is to be achieved there is no doubt that massage is most successful in the early treatment of fractures. The various movements to be used in these cases are clearly and briefly described and figured, and the progress of his own cases as described reflects credit on the skill of the author. To turn the crippled hand of a girl with Volkmann's ischæmic paralysis into a hand that can sew and darn after treatment for a year and a half is no mean achievement. Photographs of this case are given. Like most writers on massage, the author is too sanguine as to its curative powers in scoliosis, a deformity which he declares can be altogether prevented by care in detection and treatment. This is clearly the language of enthusiasm and haste. Speaking generally, we are inclined to regard the writer higher as a practical man than a theorist. More authoritative guidance than is here to be found will be required by medical men seeking to arrive at a decision as to the employment of massage in their more serious medical cases and the time at which it should be begun; but for the practice of massage they will find the book very instructive.

The Pharmacy Handbook. By F. W. CROSSLEY-HOLLAND. London: Henry Frowde and Hodder and Stoughton. 1914. Pp. 224. Price 6*s*.—This book is likely to be of less use to medical practitioners than to pharmacists; its intention is to provide the latter with useful information other than that which is obviously part of the knowledge of every pharmacist.

Tropical Hygiene for Anglo-Indians and Indians. By Sir C. PARDEY LUKIS, K.C.S.I., Director-General of the Indian Medical Service, and Major R. J. BLACKHAM, C.I.E., R.A.M.C., Hon. Surgeon to the Viceroy of India. Second edition. Illustrated. Calcutta and Simla: Thacker, Spink, and Co. 1914. Pp. 261. Price 3 rupees.—The first edition of this little book was published in 1911, and its immediate reception was so favourable that it was quickly sold out and a new edition became urgently called for. The authors have now thoroughly revised their work and brought it up to date; they have also largely rewritten a good deal of it. Instead of 10 chapters there are now 12, the two additional chapters dealing respectively with the disposal of the dead in hot countries and with the climate of the tropics. The other subjects considered and explained are the communicable diseases of the tropics, air and ventilation in hot countries, water and water-supplies, food, clothing, houses and their surroundings, the disposal of refuse, insects and disease, and disinfectants and disinfection in the tropics. The volume was originally intended to serve as a manual for the benefit of candidates for the senior certificate in Indian home hygiene of the St. John Ambulance Association, a body which has taken a large part in popular instruction in health matters, and whose certificate can now be obtained after a special curriculum adapted for the sanitary needs of India. The aim of the work is at bottom to spread among laymen the knowledge of domestic hygiene in India, where hitherto it has, unfortunately, not received sufficient attention, and to point out the chief dangers to which residents in India are exposed as well as the best means to be taken for avoiding these dangers. The high official positions held by the two collaborating authors of this volume will give great weight to their teaching, which will produce valuable results in the near future. The book covers a very wide field; it is therefore the more remarkable to find how much sound information and good advice have been concentrated in so small a space. The style of the book is concise and clear, maintaining well the interest of the reader; it cannot, in our opinion, fail to prove of great service, not only to the student of elementary hygiene, but to all Anglo-Indians and the educated classes of the native populations, if they will but give it the study which it deserves.

The Pocket Formulary for the Treatment of Disease in Children. By LUDWIG FREYBERGER, M.D. Vienna. Fourth edition. London: W. Heinemann. 1914. Pp. 260. Price 7*s*. 6*d*.—This little volume contains a great deal of information in a very small space. It affords a full list of all the drugs commonly used in the treatment of children, with their properties, uses, therapeutic action, and doses. In addition there is a therapeutic index at the end of the book. The disadvantage of all books of this kind is that in the plethora of drugs recommended in alphabetical order for any one particular disease it is difficult to make a suitable selection; for instance, in the treatment of typhoid fever 29 different drugs are recommended.

JOURNALS AND MAGAZINES.

The British Journal of Surgery. Vol. II., No. 6. October, 1914.—This number opens with a short note on James Syme, accompanied by a portrait—Mr. Corner describes the method of exploring the knee-joint by a splitting of the patella vertically. The author claims for this operation that it gives a complete view of the joint without weakening it, and allows operations upon the crucial ligaments.—A valuable collective report upon the operation of the resection of the posterior nerve roots is given by various authors with notes of 58 cases, the majority of which have not been published before. The conclusions arrived at are: that the operation is of permanent value for the abolition of spasm in paralysis of cerebral origin and a few classes of spinal origin, but that there are many limitations to its usefulness in these cases, particularly mental deficiency; that it is only of very occasional service in the cure of pain; that it has given good and lasting results in the cure of the gastric crises of tabes.—Mr. C. A. Pannett in an interesting experimental investigation about anoci-association shows under what conditions sensory shock-producing stimuli in the abdomen can be prevented from reaching the nerve centres by local anæsthesia.—A short epitome of contemporary Italian surgery is contributed by Professor Bastianelli, of Rome.—A very instructive article by Mr. Wilfred Trotter deals with chronic subdural hæmorrhage resulting from comparatively trivial injuries. He shows, too, how this condition may be recognised and how timely recognition may render curative operations possible.—Mr. Ernest Miles describes in detail, with numerous illustrations, the technique of the abdomino-perineal resection of the rectum for cancer.—A carefully worked out thesis, illustrated by many sections, on the etiology of appendicitis and gastric ulcer is given by Mr. R. G. P. Lansdown and Mr. Scott Williamson, who believe there are certain peculiarities of lymphoid tissue which the pyloric, duodenal, and appendical regions share in common, and that both gastric and duodenal ulcers and appendicitis are due to primary lymphoid infection, the ulceration of the mucous membrane being secondary.—Descriptions of visits to the clinics of Sir Watson Cheyne in London and von Eiselsberg in Vienna are full of technical and personal interest. There are also a number of cases of interest or rarity described and one instructive mistake.

The British Journal of Tuberculosis. Edited by T. N. KELYNACK.—In the October issue Professor Sheridan Delépine gives the results of the information collected by him since 1896 in connexion with the administrative work carried out in Manchester[1] and elsewhere in relation to tuberculous milk. By an analysis of statistics relating to the tuberculosis mortality in comparison with the efforts made for the reduction of tuberculous milk he is led to the conclusion that although there is not complete agreement in the results obtained by various observers as to the exact amount of human tuberculosis attributable to the consumption of tuberculous cow's milk, there is clear and cumulative evidence that cow's milk plays a very important part in the production of infantile tuberculosis in England and Scotland. Discussing surgical tuberculosis in childhood, Mr. Lawford Knaggs lays great stress upon rest in joint tuberculosis as the one agent that has stood the test of time. He does not, of course, neglect other methods, but urges that the responsibility of laying out money subscribed for hospital purposes is great, and that if it is spent in exploiting new methods of treatment it may very soon be found that it has been thrown away. He suggests that it would be wiser and more economical to proceed on old lines that have been proved to be sound, which description undoubtedly applies to the treatment of hip-joint disease by rest and extension. The Arneth Count in Pulmonary Tuberculosis, by Dr. W. E. Cooke; the Albumin Reaction of the Sputum in Pulmonary Tuberculosis, by Dr. E. G. Glover; and an account of the Tuberculosis Conference at Leeds, by Dr. Herbert de Carle Woodcock, are the other articles.

The British Review. Edited by RICHARD JOHNSON WALKER.—The stupendous war forms the staple of this periodical for October. Major G. W. Redway begins a serial article on the True Story of the War, briefly skimming the causes and elucidating the principles that compelled our intervention. He discusses the possible strategic ideas in the minds of the respective commanders, and describes the operations to the point at which General Joffre resumed the offensive that culminated in the battle of the Aisne. Paul Parsy describes the early stages of mobilisation in France. Bruce Mitford traces the relation of the Japanese to the war and deplores the suspicion and enmity which Japanese actions have encountered, and holds that Japan by her magnanimity and self-restraint has dealt a heavy blow at that grim spectre of the future world—race prejudice. The hope for Poland is laid bare by R. S. Latimer, who maintains that Poland's ideals are insured to her by the Treaty of Vienna (1815), which hitherto has been kept not at all by Germany, under whose influence Russia also has for long attempted to stamp out Polish national aspirations. Austria has not departed so widely from the principles of policy and justice, but has meted out not a little kindly treatment in her share of the divided nationality. The recent proclamation on the part of Russia, however, has renewed hope for Poland, and Mr. Latimer urges that "here to-day is a great opportunity for the mightiest emperor of the three to keep the pledge given by his ancestor, and in so doing to win to himself the allegiance of a great nation and the admiration of the world." W. M. J. Williams, writing on the financing of a great war, concludes that the field of taxation must not be widened. Property is already overtaxed, only drink and tobacco can bear further imposts, and with some aid from these income-tax will have to bear the burden. Demetrius C. Boulger records some personal war experiences. Among other articles, Hilaire Belloc reviews the reign of Pius X., the note of which was simplicity, consisting in reassertion of clear-cut principles as the rule of conduct, political as well as personal, in opposition to expediency, and ventures the prophecy that when the war is over and the liquidation of Europe is concluded his action will be seen to have been prophetic. The editor reviews the Papacy's nearly 2000 years' experience of wars, and sees in Benedict XV. an adequate minister to the needs of a new era. "E. C. K." urges that the people of Ireland must develop on their own lines, and the innate love of "glory," which they share with the French, seems to him one of the strongest reasons for instituting a national system of self government. Verse, much of it on patriotic themes, is abundantly represented in this number.

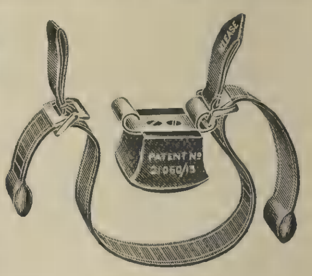
The North American Review. Edited by GEORGE HARVEY.—The October issue divides its contents into two parts, of which the first five articles deal with various aspects of the war. The remainder confines itself to the æsthetic side of life. Mr. William Elliot Griffis criticises his country's attitude towards Japan, Sir A. Quiller Couch examines the workmanship of Macbeth, and Mr. David A. Modell reviews the domestic life of Tolstoy as laid bare in his letters to his wife, pointing out that the letters afford yet another illustration of the fact that great men are apt to lead unhappy married lives. The matter with the poets, according to Mr. Robert Haven Schauffler, who inquires why the present renaissance of the poetry lover has failed as yet to bring with it a renaissance of the American poet, is that "the poet is tired." Great art demands fulness of life, and this has been unattainable because "we have been unwilling to let our poets live while they worked for us." He suggests the establishment of fellowships of creative poetry. In Life and Mind, Mr. John Burroughs examines critically the mechanistic conception of life, and makes out a strong case for the fact "that you are you and I am I, and that human life and personality can never be fully explained or accounted for in terms of the material forces."

The Journal of the East Africa and Uganda Natural History Society contains in the August issue (Vol. IV., No. 8. London: Longmans, Green, and Co. Price 4*s.*) several articles of interest to naturalists, including the African brown-bellied kingfisher, of which there is a coloured plate, by Dr. V. G. L. van Someren; Game Animals of Jubuland, by Mr. I. N. Dracopoli; and Fishes in British East Africa and Uganda, by Mr. F. G. Aflalo. Dr. Wynstone-Waters's article on the Organic Cell is continued. The doubt with which stories unsupported by evidence of the discovery of new animals are received sometimes proves to be wrong, the platypus and the okapi being cases in point, and it may be that the weird animal which has been named chemosit or nandi bear may prove eventually to have an actual existence. Anyway, Mr. A. Blaney Percival's short note on the beast is interesting. Stories in regard to the animal do not agree except in this, that it is fairly large, stands on its hind legs, is nocturnal, very fierce, and kills men or animals—by no means a scientific or illuminating description. Mr. C. W. Hobley has already in this journal referred to the "unknown," and gave a diagram of its supposed foot in an article on Some Unidentified Beasts, while Mr. G. W. Hickes has also mentioned an unknown beast seen on the Magadi railway which may or may not have been the elusive quadruped in question.

New Inventions.

AN IMPROVED TOURNIQUET: THE WESTERN.

FOR some time past in connexion with ambulance work the need has been felt for a more efficient form of tourniquet than those in general use. In the case of the indiarubber form the rubber soon perishes, and when the instrument is applied the circulation of the limb is completely restricted. In the pad-and-strap tourniquet there are three distinct weaknesses: (1) When the strap is tightened the pad is pulled out of place; (2) owing to the means to secure the appliance being a spiked buckle some relaxation of the band takes place and it is difficult to remove or adjust; and (3) the strap, being pierced by the buckle spikes, is weakened and soon wears out. The instrument here figured overcomes all these drawbacks and possesses many advantages. It consists of a pad or block of vulcanite (or other suitable material) which is affixed to a metal plate, one end of which forms an "eye" and the other an open hook. To the eye is permanently attached a special form of spikeless buckle (known as the "Bennett"), and a similar detachable buckle engages over the hook of the metal plate when the instrument is in use. Through the two runs the strap of the tourniquet, which consists of two lengths of webbing placed one over the other and stitched across at frequent intervals, the ends of the webbing being thickened so that it cannot be detached from the buckles. To apply the tourniquet the loose clip is removed from the hook, the block is placed in position, the strap is passed round the limb, and the loose clip replaced over the hook. Pressure is then exerted on both ends of the strap, and the block is forced directly downwards, the strap automatically holding at the point of greatest pressure. To remove the tourniquet the release tongues are pulled with an upward motion, when pressure is instantaneously relaxed. An additional lock is provided for use in cases in which a patient may have to be transported a considerable distance.



Messrs. Hatrick and Co., 70, St. John-street, Clerkenwell, are the makers.

LONDON: SATURDAY, OCTOBER 31, 1914.

Services by Medical Officers of Health to Military Authorities.

As a result of the issue of the War Office and Local Government Board directions, to which we referred last week, medical officers of health have considered the position which they are asked by the Government to occupy in relation to troops stationed in their areas. The duties enumerated are at first sight rather formidable. They cover such matters as the distribution of troops in billets, the sanitation of camps, the sufficiency and purity of water-supplies, and provision for cases of infectious disease among the military population. Medical officers of health who have in the past paid little attention to military hygiene may well at the beginning feel doubtful both of the value of the assistance which they can give, and of the reception which any proposals which they make may receive from commanding officers or from their colleagues on the Army Medical Staff. With regard to the latter situation cases have already been brought to our notice in which the medical officer of health has not found his appearance on the scene or his offers of assistance well received. All such difficulties, however, should now be effectively removed by the new official directions. The question whether the medical officer of health has any right of entry under Public Health Acts on military premises does not now arise. He is officially regarded as a local expert officer on the spot whose assistance is to be invited by the military, and he is given authority to report serious conditions affecting the health of the troops in his district, both to the War Office and to the Local Government Board.

As to the work required, medical officers of health are unlikely to go far wrong if they apply to the new environment the general principles of their civil action. Military conditions do not affect the underlying facts of infection and ill-health resulting from overcrowding, accumulations of refuse, excretal nuisances, presence of flies and vermin, or absence of general cleanliness. The remedy may be somewhat different in application, and standards may in some cases have to be more lenient and in others more strict. Sufficient guide on the orthodox views in these matters is, however, to hand in the admirable little manual of military hygiene issued by the War Office, and local circumstances will often enable new departures to be made with excellent results, as may already be seen in the arrangements for water-supply, latrines, and scavenging which have been extemporised in some of the provincial towns which are now occupied by billeted troops. One of the most important of the duties which the Local Government Board has placed on the medical officer of health is that of ascertaining and bringing to the notice of the local authority, for immediate action, any public services which that authority can render to the troops. Many such services at once suggest themselves: opening public baths, giving facilities for washing clothes, lending municipal clinics or dispensaries for the examination of recruits, providing evening recreation rooms, disinfecting clothing and blankets, and similar matters. The occasion should be taken also to remedy any defects in the ordinary sanitary services of the district and to coöperate with the military authorities in preventing the use of unsuitable or dangerous quarters for billeting. Isolation hospital accommodation should be seen to, and if necessary enlarged, and bakehouses, slaughter-houses, or other places used for the preparation of food for the troops should receive special attention.

In many of the important centres where troops are aggregated the new directions will be almost superfluous. Much of the work specified was begun at once after the outbreak of the war, without waiting for official warrant, and we believe that the local sanitary authorities have seldom been appealed to in vain for any practical assistance which they can give in the national emergency. It should be recognised also that in many instances, as in London, Territorial troops have had the advantage of including in their organisation medical officers of health and others who, as sanitary officers for divisions or smaller units, have themselves since their mobilisation taken such vigorous measures for the health of the soldiers under their charge as to leave very little to be supplemented by work under the new scheme. The latter, if we properly understand its intention, does not in any way remove the responsibility of the military medical service in matters affecting the health of the troops, and much military hygiene is work which cannot be done on outside advice, however good. The education of the individual soldier in the proper care of his person and environment in particular is daily work for the execution of which the army must look to its own medical service. The new troops have had to draw for their medical officers on men untrained in military work, and it is of first importance that they, like their colleagues in the regular service, should devote themselves not only to the care of sick and wounded, but also to the study of all matters affecting the daily life of the soldier, and be ready with confidence to give advice to all ranks which make for health and efficiency, and be fearless in forwarding to higher authority reports of deficiencies which in their opinion ought to be remedied. With information thus coming to army headquarters from both the military and civil sides, with local coöperation and goodwill in every locality where troops are quartered, and with increasing appreciation by combatant officers of the importance of health considerations, the outlook will be satisfactory if the individuals play their allotted part. And this we make no doubt they will do. The Sanitary Committee now appointed by the War Office should have its task appreciably lightened by the existence of the new scheme, the working of which can be periodically watched and supplemented under the advice of the Committee as experience is gained. The personnel of this Committee is announced on page 1069.

◆

The Graduated Labour Treatment of Pulmonary Tuberculosis.

WE have received a copy of an interesting report on the after-histories of patients discharged from the Brompton Hospital Sanatorium at Frimley in Surrey during the years 1905–1910. The report has been issued by four of the physicians to the Brompton Hospital who are or have been visiting physicians to the sanatorium—Dr. S. H. HABERSHON, Dr. F. J. WETHERED, Dr. P. HORTON-SMITH HARTLEY, and Dr. J. J. PERKINS, and the medical superintendent of the sanatorium, Dr. W. O. MEEK. The sanatorium was formally opened on June 25th, 1904, but it was not until the following year that the institution was in full working order. The statistics accordingly refer to the period March 8th, 1905, to Dec. 31st, 1910. The sanatorium was originally intended for 100 patients, but in 1908 the beds were increased in number, and at the present time there is accommodation for 148 patients In arriving at a conclusion as to the result of the treatment carried out at Frimley it is important to bear certain points in mind. The great majority of the patients have passed through the wards of the Brompton Hospital in London, whence if found suitable after a period of observation they have been drafted on to the sanatorium. The patients were not taken at random, but were carefully selected, only those patients being chosen who were free from fever or other serious constitutional symptoms, who possessed considerable vitality, and had already shown indications of a favourable response to treatment. So far as possible also patients with signs of limited disease were selected, although it was soon found that patients with extensive disease, but of a quiescent type, often did remarkably well. In other words, more importance lies in whether auto-inoculation is, or is not, easily induced than in the pathological stage of the disease. Only those individuals should be placed on graduated labour who can take a fair amount of exercise without exciting undue febrile response. Another point on which the physicians at Brompton lay stress is the likelihood of the patient obtaining work upon his discharge from the institution, and it early became apparent that if the patient had no work to return to after leaving the sanatorium he would almost certainly relapse quickly through inability to obtain adequate nourishment. In the introduction to the report attention is rightly drawn to the conditions under which patients are sent to Frimley, for, as the physicians remark, it would be a mistake to suppose that the results obtained there in regard to the arrest of the disease and prolongation of life give any accurate index of the economic results which might be expected if all cases of tuberculosis of the lungs were sent haphazard to sanatoriums. We are glad to see stress laid on this point; emphasis must be given to the fact that graduated labour treatment is only suitable for a certain class of case, and would be the reverse of beneficial if all patients suffering from pulmonary tuberculosis were submitted to the régime. In the early days of sanatorium treatment the idea arose that it was suitable for every variety and stage of the disease, hence much disappointment arose, and the methods adopted at Frimley would suffer a like disrepute if a careful selection was not made.

The report deals with the details of the treatment which are now known to the profession at large. Elaborate statistical tables, admirably drawn out, are given to demonstrate the results achieved. The total number of patients discharged during the six years covered by the report was 1892. The patients were communicated with at periodical intervals after they were discharged, and the results are based on the after-histories of 1674 of these cases, the remaining 218 being accounted for by 64 who only remained for a few days in the sanatorium, 91 in whom a diagnosis of pulmonary tuberculosis could not definitely be made, 19 who had suffered from pleurisy with effusion but without definite evidence of pulmonary involvement, 24 admitted for a second period of treatment, and 10 who died in the sanatorium. The object of the report is stated to be to show the proportion of the 1674 patients who during each year following their discharge have been (*a*) well and able to work; (*b*) alive; (*c*) known to be dead; and (*d*) lost sight of. Further, in order to render the statistics more reliable in each year the patients in whose sputum acid-fast bacilli were found are tabulated separately from those in whose sputum such bacilli were not present. This is a course highly to be commended, for a considerable number of physicians who have had a large experience in that disease are convinced that the only pathognomonic test for pulmonary tuberculosis is the demonstration of tubercle bacilli in the sputum. We strongly support those authorities who maintain that the results of any supposed treatment for the disease based upon cases in which the bacilli have not been so found are too fallacious to be of any value. The cases are classified from the clinical aspect, according to the number of lobes in which physical signs of disease were found on or shortly after their admission to the sanatorium. The statistical tables are divided into three series. The first deals with the after-histories of the 1674 patients who were treated at the sanatorium and discharged during the period March 8th, 1905, to Dec. 31st, 1910. The cases discharged in each year are divided into four classes: (1) and (2) "Full-time" cases, in which respectively tubercle bacilli were and were not found in the sputum; and (3) and (4) "short-time" cases under similar circumstances. In Series II. the after-histories of the "full-time" patients are further analysed in the light of the "immediate result" of treatment at the sanatorium. The third series of tables was compiled to show the after-histories of all the "full-time" cases of pulmonary tuberculosis which could be traced for a period of (*a*) five years and (*b*) four years subsequent to discharge.

Some remarks on the third series will indicate results which have been achieved. Unfortunately, a large number of cases have been lost sight of, which to some extent renders the statistics of less value than they otherwise would be, but to obviate this drawback untraced cases are eliminated in working out the percentage of results obtained. One table shows the condition of "full time" cases (tubercle bacilli present) discharged during 1905–6–7 at the end of each of the five years subsequent to discharge. During that period 292 patients were discharged; at the end of the first year 175 (65·8 per cent.) were well and able to work, 65 (24·4 per cent.) were alive, 26 (9·8 per cent.) were dead, and 26 had been lost sight of. In a similar manner statistics are given of the next three years, each year the number of cases lost sight of being deducted. Then finally the condition of 227 cases at the end of the fifth year following their discharge is given, with the result that 38·8 per cent. were still well and able to work, 14·8 per cent. were alive, and 46·6 per cent. were dead. On the other hand, with those cases in which tubercle bacilli were not found, at the end of five years 74·3 per cent. were well and able to work, 10·3 per cent. were alive, and 15·4 were dead. Taking *all* the "full time" cases together at the end of the five years 48·4 per cent. were able to work, 13·6 per cent. were alive, and 38 per cent. were dead. Now in order that any statistics of the results of treatment at one sanatorium may be satisfactorily compared with those of another institution it is essential that the figures should have been collected in exactly the same way, and that the social condition of patients, the manner in which they were selected, and their subsequent modes of life should be similar. These factors are extremely difficult to fulfil. In the instance of the Frimley Sanatorium the complete manner in which the tables are drawn up compares very favourably with the statistics of other sanatoriums in which patients are mainly those of the working classes, and we believe that the results must be taken as distinctly good. In the statistics of the German sanatoriums under the provision of the Invalidity Insurance Law during the years 1904 to 1908, at the end of five years after discharge 44 per cent. of the male and 51 per cent. of the female patients were capable of working. No distinction, however, is drawn between those cases in which tubercle bacilli were found and those in which they were not found.

In reviewing the report as a whole we consider that the methods adopted and the way in which the figures are arranged would form a good practical standard on which the reports of other sanatoriums and institutions might be drawn up, for it is only by means of uniformity that any useful comparison can be made as regards the various therapeutical measures which are adopted for the treatment of pulmonary tuberculosis.

Annotations.

"Ne quid nimis."

THE NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES.

THE inaugural meeting of the National Council for Combating Venereal Diseases will be held at the house of the Royal Society of Medicine on Nov. 11th at 4 P.M. It has been brought to the notice of the organising committee that there is an immediate need to call into being this National Council now during the continuance of the war. The provisional honorary secretaries of the committee in a communication to THE LANCET say:—"The abnormal state of the country gives rise to conditions which demand to be dealt with. There is great need of disseminating sound knowledge on this subject among the men collected together in large camps, so as to safeguard both their interests and those of the women in the vicinities. Furthermore, there is need to anticipate, and, if possible, to check that exacerbation of venereal disease which always follows in the wake of a great war. There is already occasion for action in the first of these directions; it is not yet known what other demands may occur. It is therefore felt that the National Council ought to be in a position to make an immediate response to any call that may be made to aid or supplement the efforts of those in authority. It is, therefore, because of the urgent need during war time that the inaugural meeting is now being summoned. and the organisers hope that it will meet with support." We cordially agree with the view that the time for educating the public as to the need for combating venereal disease and the methods which should be employed is exactly now. From a small and local inquiry which we made ourselves a fortnight ago into the prevalence of gonorrhœa among the recruits we received certain evidence that the existing condition of the country is favourable to the spread of venereal disease, though from several of the localities where we sought special information the answers were quite reassuring. In this connexion a well-informed correspondent suggests to us that attention should not be wholly focused on the new recruits, and that the very considerable temptation which lies round the path of the convalescent wounded must not be forgotten.

THE WAR AND THE CRUDE DRUG INDUSTRY.

THE likelihood of a scarcity in certain drugs as a result of the war is not confined to the synthetic products which have hitherto mostly emanated from German laboratories. English pharmacists have hitherto been to a very large extent dependent upon imported supplies also of crude vegetable drugs—aconite, belladonna, chamomile, digitalis, hydrastis, hyoscyamus, and valerian may be cited as examples. Yet some of these grow naturally in various parts of our islands, and probably those that do not could be cultivated. Centuries ago there were many "physic gardens" in England, chiefly in connexion with monastic houses or with the establishments of noblemen. Drug farms exist to-day in several parts of this country, but for the most part the Central European countries—Germany, Austria, and Switzerland—have sent us raw material for our vegetable medicinal preparations. The Board of Agriculture and Fisheries has now issued a very timely leaflet (No. 288) on the "Cultivation and Collection of Medicinal Plants in England," and instructions are given for the farming of such plants as an industry. It is pointed out that already since the war the price of belladonna has risen more than 100 per cent., and of many other drugs to a lesser degree. Owing, however, to the limited outlet for drugs overloading of the market is an easy matter, and coöperation between the producer and the manufacturer is counselled, as has already been advantageously practised in cinchona bark production. Of course, for those who intend to embark on the pursuit, a drying plant heated artificially is essential. The south of England is said to be especially suitable for drug-growing. It is suggested in the leaflet that a considerable demand will occur next year for many of the commoner British wild plants and other medicinal herbs that grow wild in the country, and this may open up a prospect for herb collectors, to whom farmers and landed proprietors might be induced to give access to their fields. This, of course, would only be a temporary measure that would help to meet the coming deficiency and incidentally give employment at rates more remunerative than hitherto to a certain number of competent persons; but there is every reason why in this direction, as well as in others, the opportunity afforded by the war to render ourselves less dependent upon Austria and Germany and to supply our own drug markets with home-grown products should be taken advantage of, and ultimately foreign markets might be created.

THE ATLANTIC WINTER RESORTS.

IN a generous response to an appeal by Dr. Michael C. Grabham, of Madeira (who writes from the Union Club in London), on behalf of officers invalided during the present war, the Government of Portugal have consented to make an important concession in the administration of their fiscal system. Orders have been issued which will enable visitors to enter the country freely with all their requirements for domestic use, provided that there is no intention to trade or to introduce spirits or tobacco into the country. It is obvious that the Portuguese realise that the south of Europe is not accessible just now, and that the opportunity of popularising their attractive resorts at the mouth of the Tagus—namely, Mont Estoril and Cascaes—should not be lost, and also that it would be politic to make their island of Madeira freely available to those of our sick and wounded whose convalescence may be furthered by genial climatic conditions. All these Portuguese resorts are now well equipped with good water and the food-supply is abundant, while the Union Castle and Royal Mail lines of steamers offer excellent means of communication. We hope Dr. Grabham may succeed in obtaining from the Red Cross and other funds assistance in mitigating the cost of travelling and hotel life for those who have lost their health in the service of our country, and who may wish to take advantage of the practical abatements in their favour offered by Portugal.

THE DIAGNOSIS OF PANCREATIC DISEASE.

THERE are wide variations in the character of symptoms referable to disturbed functions of the pancreas, and as long as knowledge of its purely physiological actions is incomplete it is difficult to trace to abnormal activity of this gland such general conditions. Definite signs due to the pancreas have, however, been recognised: the "acute" abdomen (hæmorrhagic pancreatitis) in some cases; in others, general wasting or deep-seated epigastric pain or "massive stools" or jaundice is noted. Diabetes, too, claims a relationship to the pancreas. Careful investigations of those functions of the gland more easily detected, together with clinical signs, are, however, accumulating evidence suggestive of glandular responsibility, and a valuable critical review of our present means of estimating pancreatic disturbance has been given by Dr. A. F. S. Sladden in the *Quarterly Journal of Medicine* (1914, vol. vii., p. 455). In the first place it may be said that no single test can alone afford infallible evidence. Several are necessary, but that this should be so is no proof that such collective data are not valuable, and it appears that reasonable conclusions may be reached by these means. The tests employed are many. They are directed to two ends: tests of external secretion and tests dependent upon other functions of the pancreas. The former concern the intestinal tract; the latter such investigations as the diastatic ferments in the urine, glycosuria, actual or potential, and adrenalin mydriasis. Each test has been reviewed by this writer in turn, and his conclusions are worth recording in a few words. Four tests aim at investigating the pancreatic juice in the neighbourhood of the duodenum. The presence or absence of trypsin (the latter signifying pancreatic disease) is detected by means of the oil-test breakfast, which causes a regurgitation of duodenal contents through the pylorus, thus enabling them to be examined—"worth an extensive trial." Duodenal intubation "from the standpoint of the practical clinician ...... open to serious objections." Sahli's test, the principle of which consists in giving a capsule containing a substance demonstrable on general absorption, the capsule being digested mainly by the pancreatic juice, and the rapidity of absorption indicating the efficiency of the gland—"value of the test very doubtful." Schmidt's beef-cube test: "evidence for reliability ...... not very convincing." Examination of fæces presents more favourable opportunities. Excess of nitrogen, "azotorrhœa," is "certainly a common feature of pancreatic disease ...... pancreatic insufficiency is the most usual cause ......" The test is, however, rather laborious. Creatorrhœa, the presence in the fæces of undigested muscle fibres, is a condition which is described as "not free from fallacies," though of "great positive significance if these are excluded." Steatorrhœa, the passage of fat in the stools, is recognisable as excessive only by microscopic aid, and chemical analysis is held to be more satisfactory. This subject is entered into fully. Amongst the conclusions as to its value it is stated that "in general, if the total fat be much over 30 per cent. of the dried fæces one suspects pancreatic insufficiency, biliary insufficiency, or intestinal anomalies of absorption or peristalsis." Glycosuria, "in conjunction with other signs, a lowered glucose tolerance lays the gland under grave suspicion, although absence ...... of alimentary glycosuria affords no proof of a healthy pancreas." Against the Cammidge test "the balance of opinion appears to be adverse," but the author thinks that it may lead to further knowledge. Of excess of diastase in the urine he writes: "There appears to be no doubt that a high diastatic value of the urine offers considerable presumptive evidence in favour of pancreatic disease, whilst a low or normal value, provided there is no renal disease, indicates a healthy pancreas." The adrenalin mydriasis test of Loewi "surpasses all in the ready and simple manner of its performance." Dr. Sladden, however, thinks it rash to lay too much stress upon the pancreas alone in this connexion. An extensive list of references adds value to the article. The conclusion suggests that several such tests, or even a few, such as the last and perhaps the diastase test of the urine, both of ready clinical application, applied on many cases must become established as of collectively considerable value.

VITAMINES.

RECENT workers appear to be attaching an immense importance to vitamines in regard to their rôle in general metabolism. Further research, indeed, is tending to show that it would be profitable to study their action from a pathogenic point of view. It is suggested, for instance, in a valuable paper on Vitamines, by H. W. Bywaters, D.Sc., published in the October number of *Science Progress*, that in cancer, in which we have a pathological new growth of tissue, a special vitamine may be concerned. The question as to whether it is possible to inhibit this new growth by careful regulation of the diet with the view of excluding the vitamine has been raised. Experimental investigation at any rate so far seems to show that the vitamines for normal and cancerous growths are not identical, and it may prove to be possible to institute a diet that shall allow normal growth to proceed but which shall inhibit cancerous growth. Dr. Bywaters suggests that the minuteness of these vitamines which are requisite to maintain normal processes of life would appear to indicate that they have something to do possibly with the production of some of the essential hormones, internal secretions, enzymes, and so forth, in the animal organism. According to careful post-mortem examination of polyneuritic pigeons Casimir Funk found that this condition is associated with an extreme atrophy of the thymus, which suggests that the vitamine in rice has to do with the stimulation of this organ which evidently exerts its chief functions during the period of growth. Altogether the relationship which appears to exist between vitamines and metabolism calls for a continued study of these interesting bodies. So far the recognition of their peculiar properties appears to threaten our rudimentary physiological principles. Consider, as Dr. Bywaters suggests, the transformation of carbohydrate into fat which takes place on such a large scale where animals for market are fed on starchy foods. The starch and soluble carbohydrates in all such foodstuffs are reduced to glucose in the alimentary tract of these animals, and yet the food containing the largest amount of assimilable carbohydrate is by no means necessarily the most fattening. This would appear to show that something else is necessary to bring about the change from glucose to fat, and the suggestion is that this is a vitamine present in the different foodstuffs contained in the outer layers of the grain. The remarkable instance is further quoted of the difference in the fattening properties of two well-known adjoining fields in the Romney marshes. The vegetation is apparently identical, but the deduction is that in one case a vitamine is at work and not in the other. Further evidence is wanted, and it is to be hoped that this direction of research will be vigorously pursued in view of the great importance of the issues involved.

THE WAR AND MEDICAL STUDIES.

THE effect of the war upon the ancient universities has been very marked. Dr. A. E. Shipley, the Master of Christ's College, Cambridge, has drawn our attention to the significant figures at that university. The matriculations at Cambridge were only 665 as against 1110 last year. Almost exactly 50 per cent. of the usual number of members in residence are away, the proportion of absentees at various colleges being from 71 per cent. at Pembroke to 26 per cent. at St. Catharine's, the proportion naturally being greatest in the case of those colleges having a high reputation for athletics. In the Cambridge Medical School the figures are such as to give some ground for uneasiness. The number of medical students entered this year is only 64 as against an average of 113 in the past three years, and even of these entries it is said that at one college noted for scientific studies only 17 out of 32 entered as medical students have come into residence. The *Times* correspondent at Oxford says that only 600 men have matriculated this October, but last October 1000 new undergraduates came into residence, and the diminution among the senior students is even more marked, the medical faculty sharing in the depletion. The University of Edinburgh, which, as at Cambridge, boasts a large medical school, is 700 men short at least. We are not yet in possession of sufficient detailed statements from the London, provincial, Scottish, and Irish medical schools to enable us to determine to what extent the deficiencies in the number of those training for medicine at Cambridge are representative of medical schools generally, but it is easy to see that if anything like a similar deficiency occurs elsewhere there must presently arise a serious shortage in the personnel of the medical profession in this country. It is not to be wondered at, in the least, that the call to arms should appeal with almost resistless force to such a body of high-spirited, physically fit, and energetic young men as are the medical students for the most part of the present day. But there is much justification at any rate for the feeling that has been expressed by the General Medical Council that the first and paramount public duty of the medical student is to complete his course and to qualify as early as possible. It must be remembered that time is of the essence of the matter in the preparation of the doctor. It is not merely one of several desirable requirements, which may, however, on adequate emergency be dispensed with without affecting the result. It is, therefore, in the highest degree desirable that the ranks of the future medical profession shall not be exhaustively drained through the abandonment, even though temporary, of their curriculum by too large a proportion of those in training for medicine.

HUMAN AND BOVINE INFECTION IN TUBERCULOSIS.

In view of the doubt that still exists as to the importance of infection derived from cattle in the production of tuberculosis in man attention may be directed to a useful summary of the cases hitherto published which bear on this problem, compiled by Park and Krumwiede[1] and published in the Reports of the New York Health Department. The total number of cases reviewed is 1511, of which over half (831) were cases of pulmonary disease. In this group bovine infection appears to be almost negligible, only four among this large number of cases showing infection from this source. Again, no instance of bovine infection was discovered among nine patients who suffered from tuberculosis of the axillary or inguinal glands, a remarkable contrast to the group of cases exhibiting cervical adenitis in which so far as subjects under 16 years of age are concerned the figures for the two sources are not far from equal—viz., 51 human and 44 bovine. If we take together all cases in which the infection appears to be abdominal in origin a still more noteworthy proportion is due to bacilli derived from cattle and presumably taken into the system with infected milk. Thus, taking all ages together there are recorded 66 of human infection against 59 of bovine, while in children under 16 there are 34 of the former to 52 of the latter—a striking preponderance. On the other hand, in opposition to the view which has been advanced that tuberculosis of bones and joints, a common affection of children, is of bovine origin, it appears that only 4 cases out of 104 of such disease at all ages were of this nature. Taking the whole number of the cases together, there were 1363 of human origin, 137 of bovine, and 11 instances of mixed infection. The importance of tuberculous milk in the causation of infection of the cervical glands is borne out by the researches of Mitchell[2] at the laboratory of the Royal College of Physicians, Edinburgh, who found that of 80 cases of cervical adenitis in children 71, or 88 per cent., were due to bovine infection. Of 12 fatal cases of tuberculosis in children, 4 in which the disease appeared to originate in the mesenteric glands were due to the same source, while 7 in which the bronchial glands were the seat of origin, and 1 case of genito-urinary disease in which the seat of original infection was not ascertainable, were caused by the human type of bacillus. Examination of the milk-supply of Edinburgh showed the presence of tubercle bacilli in 20 per cent. of the samples taken. The view generally prevailing in this country, therefore, that infection from a bovine source is a comparatively rare but by no means negligible danger, is on the whole substantiated, as against the position originally adopted by Koch that the disease in cattle is of little or no importance as a source of human tuberculosis.

AN UNCANNY EFFECT OF SHELL ARTILLERY.

More than once in the accounts of the present war reference has been made to the use of shells which on exploding deal out death on all sides, leaving the victims fixed in their last attitude of life. They are said to have been left in life-like groups, remaining in exactly the position in which they died, some in the act of shooting still levelling the rifle, others dictating despatches, others lighting a cigarette, and so forth, the whole suggesting a group of waxwork bodies at Madame Tussaud's. That dead bodies can remain in the upright position without support from without is, of course, absurd, but it is interesting to point out that the favourite modern explosive is tri-nitro-toluol, and this gives off incidentally a large volume of carbon monoxide gas, which when inspired produces a healthy pink and life-like appearance in the corpse. Imagination has probably filled in the picture as to these victims appearing to retain a living posture. It will be remembered that carbon monoxide rapidly forms a characteristic compound with the hæmoglobin of the blood, which then assumes a pink, rosy colour, owing to the formation of carboxyhæmoglobin. If a puff of tobacco smoke be directed upon a film of blood the change from red to pink is easily observed. Tri-nitro-toluol is obtained in crystalline form by the action of nitric acid on toluol, an analogue of benzene, and obtained by rectification of coal tar. The shell is filled by simply pouring the melted crystals into it, the mass then being allowed to solidify. It burns quite harmlessly and with the production of dense volumes of smoke when a light is applied to it. To get its explosive effect a detonator is employed, which is generally fulminate of mercury. Owing to the fact that it does not contain sufficient oxygen in its own molecule to burn the carbon and hydrogen completely into carbonic acid gas and water respectively, a considerable volume of carbon monoxide is produced, which may be accountable for the stories about its victims having the appearance of being alive.

CHOLERA IN AUSTRIA.

In spite of official attempts to reassure the public, says a well-informed correspondent, it seems that the cholera epidemic in Austria-Hungary has assumed serious proportions. An official communication from the Medical Department of the Ministry of War, dated Oct. 12th, refers to cases which have occurred at Vienna and Budapest, and at eight or nine provincial towns. *Die Zeit*, of Vienna, published on the following day a statement from a Budapest doctor who, while dismissing any grounds for panic, admits that the epidemic has been on a considerable scale. He ascribes the outbreak entirely to the presence in Hungary of Russian and Serbian prisoners and fugitives from the eastern provinces of the Dual Monarchy. "The area in which the epidemic has raged is a large one," our correspondent continues, "because insufficient precautions were in the first instance taken at the various concentration camps. But good results have now followed the strenuous efforts that have been made by the Hungarian doctors to combat the outbreak—efforts which have been seconded by the civil and military authorities. Prisoners now reaching Hungary are no longer allowed to pass at once into the concentration camps, but instead are domiciled in specially constructed wooden prisons and hospitals, where they are kept under a very close observation for a considerable time. Later on, if no symptoms are discovered the prisoners are transferred to the concentration camps. The deaths are less frequent and it seems certain that the worst is over." Less reassuring reports, however, continue to reach Switzerland of the extent and ravages of the epidemic. It is stated on good authority, for instance, that as many as 150 deaths from cholera have already occurred in one of the smaller Hungarian towns. The funerals of the victims, it is added, take place secretly at night.

Sir Alfred Pearce Gould has been appointed by the Senate of the University of London to act for the Vice-Chancellor, Sir Wilmot Herringham, during his absence at the seat of war as consulting physician to the British forces. Sir Bertrand Dawson has been elected Vice-Dean of the medical faculty of the University, Sir Alfred Pearce Gould being re-elected Dean.

Sir W. Watson Cheyne, President of the Royal College of Surgeons of England, will open a discussion at the Medical Society of London on Nov. 16th, at 8.30 P.M., on Surgical Experiences of the Present War. Mr. E. E. Austin, being absent on active service, will be unable to read the paper announced for Nov. 9th.

THE Bradshaw Lecture of the Royal College of Physicians of London will be delivered by Dr. Nestor Tirard on Nov. 3rd, the subject being The Study of Glycosuria. The FitzPatrick Lectures of the College will be delivered on Nov. 5th and 10th at 5 P.M. by Dr. Charles Mercier, who has chosen as his subject Leper Houses and Mediæval Hospitals.

Dr. Norman Moore, Honorary Fellow of St. Catharine's College, will deliver the Rede lecture in the Senate House of the University of Cambridge on Thursday, Nov. 12th, at 5 P.M., upon St. Bartholomew's Hospital in Peace and War.

Professor C. S. Sherrington has been elected to a professorial seat upon the Hebdomadal Council of the University of Oxford.

MEDICINE AND THE LAW.

A Quack Convicted of Manslaughter.

AT the Central Criminal Court Mr. Justice Rowlatt passed a sentence of three months' imprisonment in the second division upon Orlando Edgar Miller, convicted of the manslaughter of Miss Kate Addison Scott, a lady who was admitted to a house kept by the prisoner under the title of the "Miller Institute." Miss Scott suffered from paralysis and was treated by Miller, who appears to have described himself as a lecturer on "Higher Thought" and "Faith Healing," with various drugs, including hyoscine. Dr. W. H. Willcox in giving evidence for the prosecution ascribed death to "paralysis of the stomach and exhaustion caused by general treatment—namely, the lack of food during the early period, the administration of purgatives, and repeated injections of hyoscine." The prisoner, giving evidence on his own behalf, stated that he was an American, and claimed to have been employed by the authorities of the City of Chicago to treat persons addicted to the use of drugs and intoxicants. He stated that he had there had under his care in 18 months 1700 cases of delirium tremens, and that he had been successful in diminishing the death-rate from that cause from 80 to 1 per cent., his methods being favourably recognised by many physicians in the United States. The jury, however, convicted, and Mr. Justice Rowlatt, in passing sentence, congratulated them upon having done so. His lordship said that the conviction was of importance as showing persons who with no knowledge or with the little knowledge (which, he pointed out, is more dangerous than complete ignorance) undertake to deal with dangerous poisons that they could be found guilty of a crime in spite of rhetoric and tall talk about cures, about a wonderful mental treatment, about the "unity of the infinite and all that sort of stuff." The verdict showed that a British jury, when it found that someone had been subjected to deadly poison by an incompetent person, would go straight to the business mark and say it was manslaughter. He referred to the lightness of the sentence that he was passing upon this occasion, and intimated that if any similar case came before him in future he should not be so lenient. This warning may be commended to the consideration of many unqualified persons now endangering the lives of patients with apparent impunity.

Keats v. *Bracey Wright.*

After a trial lasting five days before Mr. Justice Bray and a special jury Mr. W. J. C. Keats recovered a verdict for £300 damages for libel against Mrs. C. A. R. Bracey Wright (Countess de Lormet) and her son, Mr. W. H. C. Bracey Wright. At the first hearing of the case the jury disagreed. The statements complained of alleged that the plaintiff had flogged with a "five-tailed lash" convalescent children in the Camberwell Infirmary, of which he is medical superintendent, and that a practice of flogging prevailed at the infirmary, the accusations being contained in an election address issued in connexion with the defendants candidature for the Camberwell board of guardians. The defendants pleaded that the statements complained of were true, and that the opinions expressed were fair comment upon matters of public interest. Mr. Keats in his evidence explained that during the 16 years he had been superintendent of the infirmary he had corrected four or five boys for continued bad behaviour, using the indiarubber tubes of a stethoscope or five strands of string tied together. Certain specific allegations with regard to the alleged chastisement of particular children he denied altogether. A series of questions was left to the jury by the learned judge, the findings on all points being in the plaintiff's favour, and judgment was given for the sum above mentioned with costs, subject to a stay of execution on terms with a view to an appeal. A rider to the verdict recommended that the correction of children in the infirmary should be reported at the next meeting of the guardians. This, it was stated by counsel, was the course now pursued at Camberwell. Mr. McCall, K.C., and Mr. A. Neilson, instructed by

Messrs. Le Brasseur and Oakley for the London and Counties Medical Protection Society, appeared on behalf of the plaintiff, and the society, as well as Mr. Keats, are to be congratulated upon the complete vindication of the latter's character thus achieved after prolonged litigation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL REPORT OF THE COUNCIL.

THE annual report of the Council of the College, which is to be presented to the annual meeting of Fellows and Members on Thursday, Nov. 19th, has now been published, and contains a record of the work accomplished by the College in its various departments during the year ending August 1st, 1914. The resolutions which were carried at the last annual meeting are recorded, together with the replies of the Council. At the meeting of the Council in March a motion was brought forward to the effect that the time had arrived when steps should be taken to enable Members to vote for the election of a limited number of members of the Council, but after a prolonged discussion this was negatived by a large majority. In February the Council were asked to take part in a deputation to the Government on the position of medical officers of health as regards security of tenure and superannuation. While declining this invitation the Council asked the President to consult with representatives of the Society of Medical Officers of Health, and after this had been done a letter was addressed to the President of the Local Government Board dealing with the question solely from the point of view of public advantage. After impartial consideration of the arguments against the proposed change the Council stated that these were not in their opinion strong enough to outweigh those in favour of the request by medical officers of health for security of tenure with a corresponding system of superannuation. Much dissatisfaction having been expressed by medical men with the suggested employment of non-qualified persons for the purpose of medical treatment under the National Insurance Act, a protest was submitted on behalf of the College to the English Insurance Commission. This protest and the reply to it are printed in the report. During the year Mr. F. Richardson Cross, Mr. D'Arcy Power, and Mr. S. G. Shattock were appointed by the Council to give evidence before the Royal Commission on Venereal Diseases: Mr. Cross giving evidence as to the effects of syphilis upon the eyes; Mr. Power on the general effects of syphilis; and Mr. Shattock upon the remote pathological effects of syphilis, the Wassermann test in the diagnosis of late effects of syphilis, and the latent distribution of syphilis.

The first annual Congregation of the American College of Surgeons at Chicago on Nov. 13th, 1913, was attended by the President, Sir Rickman Godlee, and an address of congratulation from the English College was presented. Sir Rickman Godlee also visited Toronto, where the degree of LL.D. was conferred upon him, and on his departure from New York he was presented with the gold medal of the National Institute of Social Sciences, of which he was made an honorary member. In connexion with the fifth annual session of the Clinical Congress of Surgeons of North America held in London at the close of July last demonstrations at the College were given by Professor Arthur Keith, Mr. S. G. Shattock, Sir Rickman Godlee, Mr. J. F. Colyer, and Mr. Arthur H. Cheatle, while a reception for the members of the Congress was held in the College on the afternoon of July 29th.

With regard to the Licence in Dental Surgery, it is announced that examinations will be held in future thrice instead of twice a year. The examination for the Diploma in Tropical Medicine and Hygiene, granted jointly by the College and the Royal College of Physicians of London, will in future be divided into two parts, and amended regulations have accordingly been adopted. The Jacksonian prize for the year 1913 was awarded to Mr. J. Howell Evans. The subject for the year 1915 is Congenital Dislocations of the Joints, their Pathology and Treatment. The subject for the present year is the Pathology, Diagnosis, and Treatment of Trigeminal Neuralgia, and dissertations must be delivered at the College not later than 4 o'clock P.M. on Thursday, Dec. 31st, 1914. The first award of the Sir Gilbert Blane medal under the revised regulations was made to Surgeon G. F. Syms, R.N.

The financial statement shows that the gross income of the College, exclusive of the income from trust funds, amounted to £26,833, an increase of £819 on the amount for the previous year, while the expenditure in respect of revenue amounted to £21,425, a decrease of £836 on the previous year. The receipts and expenses in connexion with the trust funds are placed this year in a separate account. While it is evident that the College is in a good financial position at the present time the Council consider that it is most important to add to its invested funds for several reasons. Among these may be mentioned: (1) the insecurity of the income derived from examination and diploma fees; (2) the continued increase in rates and taxes; (3) the growth of the museum and library and consequent increase in cost of upkeep; (4) the probability that, in course of time, it will become necessary to make extensive additions to the College buildings, at a large capital outlay, to provide further accommodation for the museum and library. During the year the number of diplomas issued was as follows: Membership, 408 (including 8 women); Fellowship, 71; Licence in Dental Surgery, 110; Diploma in Public Health, 62 (including 5 women); Diploma in Tropical Medicine, 4.

On July 9th Sir William Watson Cheyne was elected President of the College, and Sir Frederic Eve and Sir Anthony A. Bowlby Vice-Presidents.

Four years ago the Council sanctioned a scheme for the recataloguing and rearrangement of the entire pathological collection in the museum. The work of revision in the section of general pathology, to which Mr. Shattock and his assistant, Mr. Beadles, first devoted themselves, has now proceeded far enough to make this part of the museum particularly worthy of study by medical practitioners and students. As now arranged the collection of general pathology occupies 32 cases, and four more will be added. The report contains a list showing the main contents of each case, while attention is drawn to the changes, improvements, and additions which are being carried out in the physiological section which is really the counterpart of the series illustrating general pathology. The various donations of specimens made to the museum during the year are referred to in the report, and the significance of the more important of these is pointed out. It is noted that the number of visitors to the museum has considerably declined, which is partly explained by the precautions taken to admit only those who come for the purpose of serious study or enlightenment. During the period under review the supply of books and periodicals to the library was well kept up. The volumes in the library were counted early this month and were found to number 66,525. The tracts and pamphlets bound in volumes of from 10 to 20 each are estimated at about 45,000, of which number two-thirds are catalogued.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

A meeting of Fellows and Members will be held at the College in Lincoln's Inn Fields on Thursday, Nov. 19th next, at 3 o'clock P.M. The report of the Council, of which copies can be obtained on application to the secretary, will be laid before the meeting. Motions to be brought forward at the meeting must be signed by the mover, or by the mover and other Fellows and Members, and must be received by the secretary not later than Nov. 9th. A copy of the agenda will be sent on application after Nov. 16th.

LECTURE ARRANGEMENTS.

The Bradshaw Lecture for 1914 will be delivered by Sir Frederic Eve on Pancreatitis on Tuesday, Dec. 15th, at 5 P.M.

The Hunterian Oration for 1915 will be delivered by Sir William Watson Cheyne on Monday, Feb. 15th, at 4 P.M.

The Hunterian Lectures will be delivered as follows:—Professor H. Blakeway: One lecture on the Treatment of Hare-lip and Cleft Palate, Feb. 17th, at 5 P.M. Professor F. C. Pybus: One lecture on Some Infections of the Tonsil, Feb. 19th, at 5 P.M. Professor Arthur Keith: Six lectures on the Anatomy and Mechanism of the Alimentary Canal, Feb. 22nd, 24th, 26th, March 1st, 3rd, and 5th, at 5 P.M. Professor W. Sampson Handley: One lecture on Enterocolic Ileus, March 8th, at 5 P.M. Professor J. Howell

Evans: One lecture on Some Congenital Lesions of the Small Intestine, their Origin, Clinical Bearings, and Treatment, March 10th, at 5 P.M. Professor Rupert Farrant: Two lectures on the Effect of Toxins on the Tissues, March 17th and 19th, at 5 P.M.

The Arris and Gale Lectures will be delivered by Professor David Waterston: Two lectures on Further Recent Investigations in the Development of the Human Body, March 12th and 15th, at 5 P.M.; and by Dr. F. Wood Jones: One lecture on the Influence of the Arboreal Habit in the Evolution of the Reproductive System, March 22nd, at 5 P.M.

ASYLUM REPORTS.

County and City of Worcester Asylum (*Annual Report for the Year 1913–14*).—The total number of cases under treatment was 1221, the average number resident being 1069. There were admitted 142 patients, of whom 121 were direct admissions. Mr. G. M. P. Braine-Hartnell comments on the fact that in only 14·9 per cent. of the cases was a history of heredity obtained. Mental stress was noted in 15·7 per cent., senility in 10·7 per cent., and alcohol in 4·1 per cent. Sixty-six patients have been discharged, with a percentage of 32·2 of recoveries on the direct admissions. The deaths numbered 86, of which 22·1 per cent. were caused by heart disease, 17·4 per cent. by phthisis, and 15·1 per cent. by general paralysis. Mr. Braine-Hartnell remarks that the deaths from general paralysis have increased from 7·5 per cent. in 1912 to 15·1 per cent. in 1913. Post-mortem examinations were made in 85 per cent. of cases.

Bootham Park Hospital for the Insane, York (*Annual Report for the Year 1913*).—The total number of cases under treatment during the year was 175, the average daily number resident being 127, of whom 59 were males and 68 females. There were 33 direct admissions and 12 voluntary boarders. There were 10 cases transferred from other institutions, all of which were chronic, and most of them bad cases. Dr. George R. Jeffrey, the medical superintendent, is of the opinion that change of surroundings to another asylum often greatly benefits these chronic insane patients. Of the patients admitted none was in good bodily health. Dr. Jeffrey believes that rest in bed in the open air is the most rational treatment for such cases. He has found the open-air treatment especially valuable in dealing with the noisy chronic insane. It generally does away with the necessity of seclusion and sedatives. In 18 cases of the admissions a distinct history of mental stress was obtained, and in eight the age epochs were considered to be causal. Several of the cases were associated with the presence of distinct bodily conditions of disease, which were thought to be the chief cause of the mental state—thus 1 occurred during gestation, 1 during lactation, 2 with disease of the thyroid gland, 1 with influenza, 1 with diabetes, and 1 with syphilis. Four cases presented physical signs of alcoholism, without which the diagnosis of alcoholic insanity is hardly permissible. During the year 26 patients were discharged, with 45·4 per cent. of recoveries. There were 5 deaths, the proportion to the daily average population being 4·06 per cent.

Mental Hospital for the County Borough of Leicester, West Humberstone (*Annual Report for the Year ending March 31st, 1914*).—The total number of patients under treatment during the year was 1067, the average daily number resident being 860. The number of admissions was 209. The following are the principal assigned causes of insanity in the admissions: heredity, 65; mental stress, 16; alcoholic intemperance, 13; senility, 11; epilepsy, 8; and syphilis, 6. Dr. J. Francis Dixon, the medical superintendent, remarks, in connexion with the causation and prevention of insanity, that the great majority of workers in this specialty are isolated from the general community and that their experience is largely confined to the care and treatment of mental disease arising in an environment with which they are but imperfectly acquainted. The psychological line of inquiry into the causes of certain forms of insanity is assuming an increasing degree of importance and the bearing of education, occupation, heredity, environment, and the rapidly changing conditions of life generally comprise fields of promising investigation. Until such trained investigation becomes general the mass of information returned annually to the commissioners, upon which are based their statistics, must of necessity lead to very unreliable conclusions. The number of deaths was 77; and in every case the cause of death was verified by post-mortem examination. The average death-rate was 8·95 per cent. Heart disease was the cause of death in 20 cases and phthisis in 7 cases.

Royal Edinburgh Mental Hospital, Morningside (*Annual Report for the Year 1913*).—The total number of cases under treatment during the year was 1022, the average daily number resident being 773. The admissions numbered 238, and in 40 per cent. of these hereditary influences were found to be present. Senile decay was also a very noticeable feature among the admissions. Nearly 1 in every 9 admitted was over 70 years of age. Alcohol was believed to have been the exciting cause in 12·5 per cent. of the male cases and in 11·5 per cent. of the female cases. The fourth most frequent cause of insanity appeared to be syphilitic infection, which in the case of men occupies a position second only to hereditary influences, and equal in importance to alcoholic excess. Dr. George M. Robertson, the physician-superintendent, refers to the surprising information that has been obtained from the routine examination of nervous and mental cases by the Wassermann method. In an examination of 200 cases of mental deficiency, undertaken by Dr. Kate Fraser and Dr. Watson, it was found that more than half of these, of every grade of severity, suffered from syphilis. The astounding nature of this revelation can be judged by the fact that if any standard work on mental deficiency be consulted the statement is made that this disease is not an important cause of idiocy or imbecility, and that 5 per cent. would more than cover the cases to be attributed to it. The discharges numbered 59, with a recovery rate of 25 per cent. on the total number of admissions. The test of recovery employed has been a severe one. The total number of deaths was 82, making a percentage of 10·6 on the average number resident. Twenty-two of the deaths were due to general paralysis and 7 to consumption. Dr. Robertson then goes on to consider the question as to whether insanity, or rather the liability to insanity, is increasing, basing his remarks on consideration of the statistics of institutions and the reports of the 1911 Census. He takes into full account statistical fallacies, and he comes to the conclusion that there has been during the last decade a proportionate increase in the number of insane persons living the early adult and late period of life, but a decrease during the middle period. There is reason to believe that the liability to suffer from mental disease may not have increased at the early and late periods, and may not have diminished during the period of middle age. It is at this middle period that the acquired or preventable insanities chiefly occur, and therefore it is at this period that the effects of temperance, self-control, adequate nourishment, and healthier surroundings would first appear. A new departure has been made this year in the institution, which is paying for the working expenses of a physician, who receives a grant from the Carnegie Trust, whose sole duty it is to visit the homes and families of the parochial patients sent to the institution. For the first time in this country, a detailed investigation by the personal inspection and inquiries of a medical man is being made into the possible hereditary and environmental causes of the insanity of the cases admitted. The importance of this measure cannot be over-estimated.

Hertfordshire County Asylum, St. Albans (*Annual Report for the Year ending March 31st, 1914*).—The total number of cases under treatment during the year 1913 was 1008, the average daily number on the register being 836. The direct admissions numbered 152, and of these 100 were first attack cases. The recoveries amounted to 59, 53 of whom had been direct admissions in 1913 and previous years. The proportion of recoveries to the direct admissions in 1913 was 34·9 per cent. The average for the last 13 years has been 31·7 per cent. A more reliable percentage of recoveries is given by separating the "first attack cases" from the "not first attack" cases and imbeciles. The percentage of recoveries of the first attack cases from 1901 to 1913 inclusive was 30·6 per cent., and that of the "not first attack" cases for the same period 46·7 per cent. The deaths numbered 38 men and 31 women, a percentage of 8·25 on the average daily number on the register. Post-mortem examinations were made in 63 cases. Phthisis accounted for 6 deaths and heart disease for 8.

THE SERVICES.

Royal Navy Medical Service.

THE following appointments have been notified :—Deputy Surgeon-General : O. W. Andrews, retired, to the *Revenge*, on commissioning. Fleet Surgeons: G. Hewlett, retired, to Portsmouth Dockyard; and O. Rees and K. H. Jones to the *Pembroke*, additional, for disposal. Staff-Surgeons: P. T. Nicholls and W. R. Harrison to the *Victory*, additional, for disposal; and J. H. Lightfoot to the *Pembroke*, additional, for the *Cornwallis*, on commissioning. Temporary Surgeons: H. J. McCaw to the *Revenge*, on commissioning; F. P. Pocock to the *Colossus;* A. Todrick to the *Collingwood;* W. W. Rorke to the *Hercules;* A. J. MacDiarmid to the *Vanguard;* A. D. E. Bayliss to the *Iron Duke*, for the *Oak;* J. Rothwell to the *Commonwealth;* G. E. W. Lacey to the *Dominion;* A. C. Morson to the *Zealandia;* H. C. Waldo to the *Lowestoft;* H. L. G. Foxell to the *Cornwallis*, on commissioning; W. L. M. Goldie to Royal Marine Infirmary, Deal, temporary; W. R. E. Unthank to the *Wildfire*, additional, for R.N. Barracks and Sheerness Dockyard; B. H. Pain and E. I. Parry to the *Vivid*, additional, for disposal; B. Malaher to the *Wildfire*, additional, for disposal; A. B. Slater, H. Harvey, and N. F. Lloyd, all to the *Pembroke*, additional, for Chatham Hospital, additional; E. R. Bailey, W. D. Galloway, G. C. Fairchild, S. L. Harke, and E. H. Hugo, all to the *Vivid*, additional, for Plymouth Hospital, additional; and P. D. Brownfield to the *Victory*, additional, for Haslar Hospital, additional.

The undermentioned have been appointed Surgeons for temporary service in His Majesty's Fleet:—Alfred F. Adamson Henry Graeme Anderson, Walter Martin Ash, Edwin R. Bailey, Alfred D. E. Bayliss, Henry Cecil Billings, Thomas S. Bradburn, Horace George Brown, Owen D. Brownfield, Ronald Edgar Russell Burn, Henry Lambert D'Olier Duckworth, George C. Fairchild, Edward Low Fisher, R. S. French, William D. Galloway, Walter Leigh Mackinnon Goldie, Peter Morris Grundy, George Hamilton, Sydney L. Harke, Maurice H. de J. Harper, Harold Harvey, Edward H.
